An Address

ON

ACIDITY.

Delivered before the Reading Pathological Society

BY JAMES F. GOODHART, M.D. ABERD., LL.D.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—After thinking over many subjects upon which I might address you I at last decided to take up the—shall I say hackneyed?—subject of acidity. I have chosen it with some reluctance because I have on other occasions and in other places introduced it into addresses although not in the dominant way which I propose to myself on the present occasion. But I do not find that the opinions which I shall advance (they are not mine only or originally) are as yet, at any rate, generally accepted, and *yet I believe them* to be true. Everyone who holds a pronounced opinion of any kind is always sure that he is right and that everyone else is wrong, and I should not be surprised if a majority of my hearers this evening stood in this relation to me of "everyone else" This, at any rate, may serve to rouse your interest.

Now there are several kinds of acidity. I may say that I am going to treat my subject from an entirely clinical standpoint. The complaint, for example, is often made that this or that individual has such an acid taste in the mouth; another lot of complainants will tell you that they cannot take anything acid; another group will assert that such-and-such articles of food, maybe even common articles of diet, will turn *acid*. As to these perverted tastes or sensations I am really not able to give you any information as to their cause, nor can you, I expect, do any better for me, for although both patient and practitioner are too often satisfied with ascribing such a state of things to the *liver* I am not clear that such an ascription helps one much, and still less so that it is *correct* But if *you suffer from acidity*, it practically means for all of us that it is uric acidity, and it is of uric acidity alone that I intend to speak to-day. I will begin by giving you the notes of a case that I was able to observe under unusually favourable circumstances, for the patient was much interested in his multitudinous symptoms and active-minded enough to record them intelligently.

A man between 50 and 60 years of age, apparently in excellent health, a hard worker, and a most abstemious liver—for he drank nothing alcoholic and lived largely on milk foods, of which he had always been fond and digested excellently—was taken suddenly, perhaps after exposure to the poison of influenza, with a general tenderness of some bad teeth, which chopped about in a most erratic way, being now in this tooth and now in that, the affection leaving one point completely when another was attacked. Within a day or two he was awakened suddenly in the night with a feeling of extreme distension under the diaphragm; there was no pain, but the distension was so great that he felt as if he must burst and his breathing was hampered. The attack passed off within a few minutes and he went to sleep, not, however, before he had noticed that his toothache had suddenly and completely gone. Two days later a similar seizure occurred of a more severe character, leaving behind it a soreness in the epigastrium, but with this exception—it, like the previous attack, vanished never to return He now began to have profuse night-sweats, chiefly associated with sudden uncontrollable panics, which would wake him up suddenly between 2 A M. and 3 A M. and render him absolutely sleepless for the rest of the night. He then noticed for the first time that he was passing a quantity of uric acid in his urine, entirely confined to the urine first passed on rising in the morning. As there was still a considerable amount of soreness in the epigastrium resulting from the nocturnal attack he dieted himself for many days, exclusively on toast-and butter, milk, junket, bread-and-milk, custard and rice puddings, but the uric acid in his urine (expressed as obvious sand) became more and more abundant, and seemed to coincide in this respect with increasing nervous depression He now had another freak, and for a few days had a "paroxysmal toothache," as he described it, in his *chest*. Every few minutes throughout the day and night, when awake to notice it, he had a momentary twinge of pain behind the sternum, associated with a sudden glow or flush over the head. This was apparently angina-like in its character, but there was not the least disturbance of the heart's action, and walking and even climbing hills made not the least difference in its coming or going. This condition would last perhaps 24 hours or so and then cease, leaving him particularly well, and after two or three recurrences it ceased altogether, to be replaced by a similar sort of pain in the abdomen, which for many weeks kept him in a state of great discomfort and distress, being associated, as it was, with a horrible feeling of "gone-ness" in the epigastrium and so much hyperæsthesia of the intestine that the slightest peristalsis seemed to become obvious and discomforting. Added to this he had obstinate constipation, quite foreign to his habit, and any attempt to counteract this instead of bettering matters added greatly to his discomfort.

Weir Mitchell, in his latest book "Characteristics," makes one of his puppets express the opinion that no man dies triumphant with disease below the diaphragm, and I am sure that my patient would endorse this statement; for although he is not dead, the misery and dejection that accompanied the exaggerated consciousness of the workings inside his abdominal casket were often extreme. Several interesting observations, as it seems to me, were made by my friend. He did not consider that there is any *continuous* peristalsis in the intestine. It appeared to him that the propulsion onwards of the food is accomplished in shifts. For from two to three hours after food there was rest in the abdomen; then on came the pain and discomfort. Thus if there were three meals there were three shifts and the absence of any one meal was likely to delay the arrival of the coal at the mouth of the pit.

The intestine would appear to be an organism of the most methodical habits, whether these be unduly active or unduly sluggish. We all know that this is so from clinical experience. A lady came to me the other day with that early morning looseness which so often exists in the nervous from say 5 or 6 A M. to 11 A.M., and then ceases for the remainder of the day. It had existed for a year or more. I have seen several cases, male and female, where this had gone on for years and had become a distinct handicap to the pleasure of living, and yet it is well nigh impossible to cure it, for it is clearly a faulty habit of the sensori-motor centres.

The patient also noticed that, for him at any rate, there was no average as regards the quantity of the alvine output. On some days there was much but on others little. So, also, on some days there were pellets, sometimes bullets or larger, sometimes tape strings, and so on He was always, in fact, receiving unpleasant suggestions as to the condition and amplitude of his vitals until he accepted the axiom that I gave him to do as the dog does—he never looks behind him. By this he established the *fact that the import of these* diurnal variations is very much what the mind makes them and that they are no absolute guide to the state of the viscera which puts them forth.

But these are digressions. During all this time the patient was keeping to a milk diet and the uric acid output, although varying and most energetically so, was nevertheless not obviously influenced by the diet, and inasmuch as he did not improve a *volte face* was ordered and a meat diet was substituted for much of the farinaceous food hitherto taken. He now had meat twice and even three times a day. All green vegetables were excluded from the diet because for the time being they seemed to cause flatulence and more discomfort, and he was allowed only a small quantity of fluid at his meals for a similar reason. From this time he gradually increased the quantity of food taken, until he ate much more largely than he had ever before done, and he also took on and off for two or three days at a time, a glass of port wine at 11 A.M. and beer or cider for dinner. Under this *régime* all the uric acid sand disappeared from the urine and he recovered his health. Since then he has continued to live much more freely than he had ever before done in the matter of meat, he eats less starchy food, takes an occasional glass of beer or cider—a thing he had not done for years—and he keeps well. One other point may be mentioned, although it is too large to be dealt with here—it is that he was distinctly not so well if he indulged in any brisk exercise.

Now, I have given this case in detail because it seems to me, first, of interest in itself, and, next and more particularly for my present purpose, because of the conditions under which gravel appeared in the urine. In itself it is worthy of note because here was a man of by no means what would have been called a 'nervous' temperament, who suddenly passed into a condition, possibly from overwork, possibly from influenza, in which he became the sport of neuralgias, now in the teeth, now in the head, now in the thorax, or in the stomach, the intestine or the diaphragm. And I suppose that *insomnia may be considered* a similar condition, for it is an unnatural alertness of brain cells which ought to be paroxysmally sluggish I do not doubt that the case is what most men would unhesitatingly call a case of uric acidity or irregular gout. It has all the characteristics of that affection—the neuralgic type of the disease, the rapid substitution of one neuralgia for another, of one nerve-storm for another, and the rapid change from a feeling of perfect health to that of positive gloom. And I would have you particularly to note that it occurred in a man who could hardly be living on a diet less calculated to produce uric acid according to usually accepted doctrines. He was a small eater and his diet was mostly milk, milk puddings, bread-and-butter, vegetables, and fruit. Meat would hardly on an average have supplied two ounces to his daily diet, yet uric acid appeared in quantity. He dieted himself still more rigorously, to the practical exclusion of meat and for a time even of fish, and he got worse instead of better, and so he remained for several weeks, rest notwithstanding, until, indeed, he commenced to live more generously and particularly so in the matter of meat and stimulants. It therefore opens up the questions which I want to discuss of uric acid and acidity and the treatment, if any, that best befits it

Now, of course the strictly chemical theory of acidity is this—that it is a mere question of chemical equations and combination. So much C and H and N and O are put in and so much C and H and N and O are given out in some or other form, and therefore excess of nitrogenous products taken in will lead to excess of nitrogenous products being given out; and therefore those articles of diet which give an excess of nitrogen will above all offend in this way. Thus it is said that meat is the chief offender in the production of uric acid, and that uric acid or one of its congeners getting into the blood poisons the tissues and so produces all the multiform symptoms—nervous, hepatic, renal, cardiac, and so on—which are ascribed to it in such truly liberal fashion.

Now, I am not here to-night to say that this is not true I am here to contend that it is only very roughly true. True, perhaps, in the same sense that the artist's preliminary sketch in charcoal is to the finished picture as it hangs upon the walls of the Academy I should call this the view of pure chemistry; but then our problem lies not merely in chemistry, but in *animal chemistry*, and that is a very different, or at any rate less demonstrable and certain, matter. And thus it is that clinical experience has to be taken into account; and in giving, as it does, a more comprehensive view, adds, unfortunately, much to our difficulty of forming positive opinions. And in this regard I want you to think for a minute of how living a thing is uric acid. I should call it one of the most fickle of animal products. Remember how paroxysmal it is; that it will alternate in some so that at one time there shall be a highly acid and uric acid urine and at another a *feebly* acid, or neutral, or even alkaline, liquid containing phosphates. And, curiously enough, just as I have written this there comes into my room an old friend who has been long troubled with acidity and who has to my knowledge often passed uric acid, but who after a course of waters has lately been passing a neutral urine and on one occasion has passed an appreciable quantity of sugar—that is, 20 grains to the pint. So that he fitly comes in to link on my previous statement with the remark which I have next to make—that the passage of sand will often alternate with the passage of sugar, and particularly so with the glycosuria of the declining decades of life.

Then, again, uric acid will appear in the urine in quite remarkable fluxes in the course of chronic renal disease. I have several times, too, seen a fatal attack of renal disease *begin*, as one is obliged to say—although possibly not accurately so, for acute disease too often begins in pre-existing chronic change—by the appearance of a quantity of uric acid in the urine, and this has subsided to give place to a load of albumin. The occurrence of uric acid in the urine is well known in the early stages of chronic renal disease, and this may well be taken to suggest, as some have suggested, that the appearance of uric acid in the urine at *any* time is an indication of defective action on the part of the kidney. And, indeed, I see little reason to take exception to that view, but even if it be so we yet need to know what it is that *makes* the kidney defective, not only in those in whom by reason of age and other causes defect might naturally be expected, but even at all periods of life, from early infancy to old age—what it is that regulates function in this way so that at one hour one may say uric acid is *poured* out and at another has vanished like a dream. And does not this so frequent occurrence of uric acid in the urine, surely almost as common in young children—not uncommon even in babies—as in adults of all ages, suggest the consideration of the question, can an occurrence of such frequency be such a harmful thing after all? May we not rather be inclined to feel that it is no more at any rate than a fit of bad temper that needs no treatment by heroic measures unless the circumstances are exceptional? And, indeed, this interpolation to some extent suggests the answer that I should give to the reason of the appearance of this stormy petrel of pathology.

I am sometimes asked the reason of the fact that pain is often so much worse at night than in the daytime and that without the cause ceasing the pain will yet vary from time to time, and the reasonable answer seems to be because all function, even life itself, is but an interrupted current. We look, we hope, we pray for the future to disclose that *continuous* existence in which the hour of depression, of pain, of loneliness, of void shall no longer be the necessary complement of energy, of *bien être*, of oneness and fulfilment. And so I think about uric acid; its vagaries of appearance seem to me to be much better explained by some perverted or ill-regulated physiological processes behind it, than by that of untimely or ill-judged stoking. I must add, too, that we know that the properties of uric acid are not poisonous, for it exists in excess or is produced in several diseases without any symptoms of "acidity" And the clinical picture of cases tells the same tale, for with what body do they come? One has been already narrated

Take now the last case that has come before me—the case of a man who has lived a hard and anxious life and who has seen many physicians. He tells me that he has always been highly strung—a beautiful picture, or poem, or music, would always move him to tears. He is restless and fidgety beyond control; sometimes he is quite beside himself. His urine from time to time contains a quantity of uric acid; at others, and particularly after what he calls his storms, he passes the low specific gravity water so well known and which Dr. Haig has shown is so often associated with the formation of uric acid. Bodily this man is in a very fair state of nutrition, but he is wearing out unquestionably in his nervous textures, and one may suspect also in others, for he has one of the most marked conditions of arcus senilis that I have ever seen. Still, so far as the working of his individual organs go there is no evidence in any of his other functions that they are at present really defective.

Take yet another case, within the last few pages of my note-book—that of a little girl, aged eight and a half years. She has grown enormously and far beyond the size for her age. She is morbidly excitable and is subject to uncontrollable fits of screaming. Anything exciting will send her off, both things she takes pleasure in and wants to do as well as those that are distasteful. She is always "so tired." She is constipated and her urine often contains a copious deposit of red sand. The case seemed to me purely one of an excitable nervous system made worse by the exhaustion engendered by a period of inordinate growth.

Here is another case of a woman, aged 52 years. All her people are gouty and one sister died from gout The patient has been subject at times to attacks of insomnia for several years and for one of them she came to me. She has a heavy giddy feeling in the back of the head and spine; her head feels alive; she has fits of melancholy at one time and of excitement at another. She has had a lot of domestic worry lately, and she attributes all her trouble now existing to that. She is a woman of fullish habit and is said by her medical attendant to be fond of the good things of this life, but on careful inquiry I cannot ascertain that she is at all a heavy or gross feeder and she takes only a tablespoonful of whisky twice a day at her meals. To eliminate all doubt as to the matter of food and drinks I cut off all whisky, and ordered light foods only, but although she was a little better she did not permanently improve and uric acid was still as abundant on occasions in her urine as ever. Then a little fresh worry occurred and she was as bad as ever, her head going wild, and when it did, so her stomach would go wild also, and she would have attacks of what she called "epigastric bouleversement." After a little while she got a definite attack of gout, whereupon she had a spell of slight betterment and then she relapsed into her old state again. She has been dieted carefully and has, I believe, paid strict attention to orders, for she is terrified at her attacks and would go through any misery to get rid of them. She has also had many remedies including waters but without much obvious effect upon the course of her disease. She now wants to undergo a thorough course for the gout, although there can be no doubt that she has already tried more than once that favourite prescription, but she is still a convinced believer in her acidity, and wants to carry out again that plan which promises so much and achieves so little.

One more case I must give. It is that of a man 47 years of age, at the top of the tree in his profession—a position which has been achieved by continuous hard mental work and in spite of the fact that there has not been a day in all the 20 years that he has not loathed his "trade," as he calls it. He came to me because of a bitter taste in his mouth which he put down to "acidity," created, as he supposed, by a pint of claret taken daily at dinner. He has lately lost weight because he has had an unusual degree of strain and stress of work. He is spare and dark. His stomach is easily upset, he is sick easily, and he has to get up at night to pass his urine. I had a long talk with him, for he was a most interesting man and I am sure that he is a most careful liver, his diet being chiefly milk and milk food. He thinks that he has created his "acidity." He is rather great on acidity, but he takes most sensible views of it and is fully confident that the bed rock of his ailment, as the Americans say, is his overwork. Still he wants to "get this acid out of him" and asks about piperazine and all the latest drugs which are supposed to perform this service for cracked, crabbed and suffering humanity. He has a chronic lumbago about which I am not altogether happy, particularly as his radial arteries are rather thick and when lying down flat his impulse is in the sixth space outside the nipple. But the sounds are natural and his urine although 1024 and containing uric acid is free from either albumin or sugar. This is a case where the urine sometimes contains phosphates and sometimes uric acid in excess. I gave him no medicine as all physic upsets him, but advised more meat and Contrexéville water in the place of so much milk stuff, and, best of all, a long and absolute holiday. He said on leaving me, "By the bye, I *must* have a little sweet," and I said, "*By all means*, a little won't hurt you."

And talking of this case reminds me that only the other day there came to me a young man who also was an adept at acidity. He was of course a highly nervous fellow, full of all sorts of fads and fancies, but what particularly amused me was that he complained of a pain in his side which was *not* acidity, "it was something quite different from that." This was so precise a statement on what is usually most indefinite, that I at once dropped upon it hoping thereby to obtain information on the position of the manufactory of acidity. But, alas! no, the comparison of the two pains had exhausted the descriptive power of my friend, and as all he could tell me about the pain with which he compared it was that he feared it was due to some carbon that had got down into his lungs from his habit of inhaling tobacco smoke, which he has given up for many months, the pursuit of the subject did not promise any adequate return for more expenditure of time.

I will not weary you with any more cases. You all know them as well as I do, for these patients come into your rooms one after the other and surely the day of a busy medical man seldom passes without one or more coming within his ken.

How do we treat these cases? Now, I have been interested in this question many years, so I am not speaking hurriedly, and I have come to be certain that in the majority of cases of uric acidity it is scarcely a matter of diet at all. But this is not the common opinion. I shall probably do this meeting no injustice when I estimate that the majority, probably the large majority, when a man is found to be passing uric acid look upon it as a matter of diet *exclusively*. I want you all to go back upon your experience, to put away all that you have read and seen through other people's spectacles, and to observe again afresh and then to answer the question, Is it so?

While I was thinking over this address a medical man came to me about a relative and while we were waiting or talking this gentleman introduced the subject of his own health—I think it came out in relation to the matter of the family tendencies of his relative. He told me that he was nervous, but what concerned him most was that he had "a lot of uric acid floating about in the system," as he expressed it. He had gone into the matter very *thoroughly*; he had read everything, had tried every remedy that had ever been suggested, and had tried all sorts of systems of treatment, and he had come to just the same conclusion as I have done—that he could not tell what determined the production or appearance of uric acid, but he did not think that he had got much help from diet.

I have notes of another patient, a most intelligent woman, who had seen many people for uric acid and she asked me, bluntly, if I knew what led to the formation of this product, and when I said I did not know she said, that she had made careful observations on herself for some long time, and that she had come to the conclusion that it was impossible to say why the product appeared. She was certain that it had nothing to do with diet, and she was sure that in her case the catamenial period *had something to do* with it.

The very vagaries of its appearance are enough to make us pause and inquire into the reality of this dietetic theory. In one group it is this or that form of liquor. One man will tell you that he never can touch champagne lest he have gout, which for the most part means what we call irregular gout—that is, uric acid gravel in the urine—and various aches and pains in his fingers and toes or in his neck or his back. In another case it is a glass of hock that is the poison (it is always a single glass, mind you), or of sherry, or of beer. With another long list of sufferers sugar is the fatal thing, or potato (I suppose because it is a typical starch). I think it can be only a small part of civilised society that ever touches a potato. It, indeed, must be a very inferior class of article to judge by the scorn which so frequently accompanies the statement, "Of course, I never touch potatoes." With others, in similar fashion, it is meats that are tabooed. "I never touch butchers' meat" is equally commonly heard, and I have sometimes wondered why the poor butcher should be so commonly conjugated with his meats in this chorus of universal disapprobation. I might, of course, go on all day, for the full enumeration of the various articles of diet that now and again have been associated in the minds of patients with uric acid; indeed, so many are they, that I often say that I have only met with two articles of diet which I have never known to be complained of, and these are toast—no! I beg its pardon, I should have said "well torrified bread" (which is, I suppose, not toast but cinders)—and the other article is whisky.

We cut out of the diet sheet all red meat. But why only red meat? Surely, it is very inconsistent to reject this alone of all the nitrogenous products which are supplied to us. Why not exclude fish and fowl and eggs and all the vegetable albumins? These things are allowed because they contain less extractives. But is this rule so universal as we make it? Emphatically no. Stomachs are very individual organs—some oh! so touchy; others wonderfully obliging. I have several times been surprised to find an individual stomach when desperately ill craving for a slice of bacon, and what is more to have received its master's commands, obeyed them, and to have derived no hurt from its indulgence. Now, *a priori* one would certainly think that few things could be more indigestible than the meat of bacon, because it has not by any means always been *fat* bacon, it has been *fried* bacon. And I have always supposed that the reason why so much of civilised humanity indulges in it, especially at breakfast, is because a sort of intuitive consciousness has come upon it that the stomach is more ready to cope with the indigestible at a time when it is fresh from its nocturnal rest. But if sick stomachs find themselves equal to bacon, surely it behoves us to think twice before we deprive so capable a servant of the delights of a nice piece of juicy red meat. My own opinion is that there is nothing more digestible or void of offence in any way, and, as I have said before and got hauled over the coals for it, I care not whether it be beef or mutton or pork, only in the latter case I should bar the attribute of redness, for reasons, however, other than digestibility. Personally I have great doubts whether the chicken that we are all so fond of ordering to an invalid is any more digestible than mutton or beef, though as regards our present subject I suppose it may be taken as proved that it ranks lower in the scale of urea-forming products than do beef and mutton.

And then as regards vegetable albumins, what I have just said accords with my own experience, as I do not doubt that it accords with yours, for it is impossible to be otherwise than sure that in children (who are, of course, seldom large meat eaters) it is not those who are fed fully on meat who especially pass uric acid crystals; and you do no good by cutting them off all meat, as is very commonly done. Over and over again I have seen children deprived of all meat because of the passing of uric acid, and parents in a state of great anxiety, as if some dreadful disease were sapping the vitals of their offspring, but there is seldom anything to be alarmed at or that calls for any serious change in their habits of life. Such children are, I think, often pallid, pasty-looking, and usually want some little attention to their diet, in the manner in which it is eaten, and in their general hygiene, but that is all, and it is generally the better plan to increase their meat (plain cooked, roast or boiled; not beef-tea or beef extracts or jellies, to which parents often fly between meals in poor-looking children), make them drink more water, and diminish correspondingly the quantity of starch food taken. That is the practice which I have carried out for a long time and I have never seen reason to regret it. Regulate the diet all round, as the late Sir William Roberts wisely said; it is not the fault so much of any special food. Children will pass uric acid even upon an excess of milk.

And I think that perhaps we can see that all this is reasonable enough if we remember what is the state of the case as regards glycosuria, for the formation of uric acid and the formation of sugar seem to me to run on somewhat parallel lines. Nothing seems more sure in medicine or physiology than this—that you may remove *all* the sugar from the *intake* and that you will still get sugar in the *output*. Or, to take the less precise field of clinical experience, in the glycosuria of old people you will get many a case where the exclusion of sugar from the diet seems to make very little difference as to whether sugar appears in the urine or not. I have a case of this sort vividly before my mind now. This old lady is inordinately fond of sugar and it is impossible to keep her away from things that contain it, but it makes very little difference. Sugar is absent for long times together and then, without evident reason, it re-appears. The same thing holds with the diabetes of younger folk, for although you can diminish the output very largely, the disease is yet paroxysmal or fitful and the quantity of the output will not very accurately accord with the intake. I assert that it is exactly the same for uric acid. Over and over again have I seen people dieted up to the extreme point of misery—and if you have as yet no idea how miserable a rigid diet makes you, try it at once for a month and see; you will be a much better practitioner at the end of the month than you were at the beginning—and they were yet passing uric acid crystals almost by the spoonful.

It seems to me, therefore, clear that if you could absolutely exclude urea-forming products from the diet sheet you would yet find the human economy turning out uric acid, and although you might reduce the capital quantity in some cases, you could not do even that in everybody. In other words, uric acid is an *ash*, common to the many metabolic processes going on in the body. In this process and in that of the many taking place, re-arrangements of the elementary or primary combinations are constantly going on, new conjugations are formed, and the required elements are also stolen from the stockpot if they cannot be obtained from, so to speak, a legitimate current supply, by such other elements as are in a state of hunger and yearning. It is important to bear in mind, too, that there may be two opposite metabolic defects, but there is the defective metabolism of want of supply as well as the defective metabolism of excess and you may induce a uric acid excess as well by the one as by the other.

Who is there who cannot remember, when he thinks back on what he has seen, of the many times there has come before him a spare, wan, anxious man or woman, a martyr to headache, to indigestion, to constipation, to gravel, to melancholy, whose every organ seemed to have been created for the sole purpose of exasperating its master, so full was he or she of the misdeeds of the one and the other. And who can doubt that in these the pathology is not one of excess?—the whole bearing of the patient forbids such a possibility. These people have almost invariably dropped out of the dietary one food after another because it was indigestible or because it produced gravel, yet, starved as they are, the uric acid still appears in the urine. The whole head is sick and the heart faint, and this is what is the matter with these people, whether you call it gout or acidity or any other name, and what most of these people want is a good fat chop and a glass of stout. "Oh, but that would never do; it would give me a bilious attack," as if, granting that their forecast is correct, a bilious attack occasionally would represent a tithe of their present misery.

It always seems to me that we see things in medicine far too much with the eyes of other people than with our own, and thus all treatment coming from authority tends to become stereotyped. There is surely a good illustration of this in diet sheets; you can hear it from patient after patient as they come before you. I have a diet sheet now before me for persons suffering from gravel which has received the imprimatur of one of our most able physicians. I am willing to admit that it is not a bad one as diet sheets run, but let us look into it for a minute. And first of all it is a printed one. That, of course, means that Dick, Tom, and Harry all get the same if suffering from gravel. Can I have any stronger corroboration of my contention that gravel is made a sort of, shall I say, demoniacal possession and that it cometh not out of us but by prayer and fasting? But I want to drive home to night that Dick's gravel and Tom's gravel and Harry's gravel are three separate devils most probably, and that while prayer, which would, I should hope, include repentance, might be good for one and fasting for another, by the time you had arrived at your third case you certainly ought to be ordering stout and oysters or any other renovating dish that you might personally believe in. I protest with all my might against the absurdity of humanity being made to run in common grooves like this, and on such a very personal matter, as the food we eat. Well, then, of course, from what I have already said, my three poor friends being afflicted with that terrible disease "the gravel" must avoid eating sugar in every shape or form. And for what reason? I suppose the compiler had in his mind that sugar goes to form glycocine, and glycocine is the material out of which uric acid is formed. Whether this be the case, whether this be even a fair statement of the case, I will not be sure, for I am professedly treating the question from the standpoint of every-day practice only; but if it be so I should still hold that, after all, sugar is not a poison, and this wholesale condemnation of a wholesome article of food can hardly be other than a fad. By all means cut off sugar on good reason shown for this or that individual; but I know this, that there is many a gravelly one who can take sugar in moderation as an article of food and not be a bit the worse for it. Nay, more, there are some of the "gravelly" who cannot do without sugar. "Oh, let me have a little sweet," as my patient said. I see it stated in the Life of Sir John E. Millais that Rogers the poet took a parental interest in him and that he used to say to his footman, "Put three lumps of sugar into Mr. Millais's tea," when poor Mr Millais visited him; "he ought to like sugar, he is too thin." Rogers, although eccentric, was a wise man; and oh! my hearers, those of you to whom this appeal comes home do reflect that there are some of us who triumph over old age in our liking for sugar, and why have you got your knife into it so? Let me tell you in your own interest that if ever you are called in to attend me, and you cut me off my sugar I will promptly go and see a consulting physician without telling you, and come back and call in your most bitter rival. What more can I say to show how strongly I feel on this excellent food-stuff?

I see that fat stands next on this list of "dreadfuls," and for the same reason, I suppose, its glycocinic leanings, but the wisdom of this exclusion seems to me to be cancelled by the allowance of butter in the "may eat," and the exclusion of cream amongst the drinks. And here I am in for another crusade. I am not exaggerating in the least when I say that people come into my room one after the other to tell me that their medical attendant has told them never to touch fat. There can be no doubt about it that there is a routine order abroad never to touch this material. I will not say that it is specially to persons who pass uric acid that it is given—it is mostly to those who are said to suffer from their liver. Well, we are each of us entitled to our own opinion, and I do not want to tread roughly upon the cherished opinions of anyone; all I want to be sure of is, that they are your own opinions and not those of some, perhaps brilliant, teacher passed on and assimilated without correction by your own thought and experience. But even then I want you to think the matter over once more and to give it another trial. And when the next poor sufferer, with, perhaps, a liver, or what not, tells you that he never takes fat and that cream would make him bilious, just gently murmur that even infants can digest cream easily and that it is really a most excellent food for the liver. And so it is, and so is good olive oil, but it generally happens that when I order it, as I often do—for it is much more palatable than cod-liver oil—and by the bye it is a funny thing that when the liver depends so much for its substance on fat that all fat should be taken from the food in case the liver should be upset,—whenever I order it, I say, the patient holds up his hands in horror at the suggestion because his medical attendant has forbidden it. There are several other articles excluded that cause me much wonder; such are herrings and eels (the latter being one of the most tender and delicate of foods if properly cooked), but I must pass on to my third crusade, and this has to do with the "may drink."

Now in this list there is nothing to take exception to, except that it is not hinted that it is at least *possible* that the person who passes gravel may be the better without any alcoholic beverage. He is told that he may have a little light wine—Moselle, Hock, Chablis, Sauterne, or cider in small quantities. But in ordering, or rather permitting, light wines and nothing else this diet sheet surely does not follow the usual routine of the profession. As a rule, the profession forbids all wines of every sort and tells the patient to drink whisky. And as I have said before, although often professing the greatest possible dislike to it, he yet drinks it with astonishing facility. There can be no possible mistake about this. I have had ample opportunities of forming an opinion and I say that people hardly ever drink beer now; they are frightened at nearly all wines; so that they run like sheep after the last new white wine that the fashionable medical man of the time orders them, and most of them eventually discard all wines and take—on the whole and with few exceptions—very complacently to whisky. Again I ask, Can a routine treatment of this kind, a routine prescription which I am persuaded must often come tumbling out of the mouth of the prescriber without any thought, be fitted to Dick and Tom and Harry indiscriminately? What can there be of harm in a glass of good light wine or in a glass of light beer that is not present, only more so, in spirits? Mind, I am not holding a brief for either the one or the other, but I am quite sure that if a man requires any stimulant at all—a matter he must decide by experiment for himself, for I maintain that no medical man can tell him—he will often be the better for a glass of wine, than he will be for the now commonly substituted whisky. And in nothing more than this, does the question of the individuality of disease come in. What a man drinks, if he passes uric acid, is, in my opinion, a much more important matter than what he eats. A large number of those suffering from acidity had better take no alcoholic liquor of any kind; others are better for some. It should always be a most moderate quantity. To many champagne seems to be a poison, to others it is the most wholesome wine, and they drink it year after year and do well upon it. Some, again, do well upon port, although this is an exceptional thing, but claret and the lighter wines are the more generally useful. I do not think there can be any doubt that there are some who cannot digest wine and yet who do require some little stimulant to get through their work, and for these whisky or brandy well diluted comes in as a valuable help. I am not objecting at all to its well-considered use in such cases as these; what I am objecting to is that a glass of good wine should be so universally discarded and ever so much more alcohol taken in the shape of whisky. And, moreover, this prescription of the medical man is changing the habits of the people. We used to drink beer, we now drink whisky; and I am sorry to say that this is the case for the young men as well as the old. The young men in our large towns will often confess to three or four glasses of this strong and, to them, poisonous drink in the course of the day without having the least idea of the harm that is accruing to them. And I think we medical men are largely responsible for this state of things. We tell everybody to drink whisky. A well-known medical man in Brussels came to see me the other day and he was asking about his drinks. He told me that he had got some very good wine, but that he found over here that we all ordered whisky and that it was whisky everywhere. Even the waiters at hotels and dinner-parties brought you a whisky-and-soda almost before you had asked for it. And he was not far from the truth. People are told to drink whisky because, forsooth, it is the purest spirit, and young and old are drinking it. My idea about drinks is, first consider whether you would not be better without anything and, that decided in the negative, then let the young man drink his beer, the middle-aged his wine, and the old man his toddy. I am, of course, talking of the daily habit. An occasional glass of anything hurts nobody, even if it should make one think he has a pain in his great toe on the next morning.

Thus far it will have been gathered from what I have said that uric acid is not a product to be eliminated so much as to be prevented, but the results of sending patients to foreign spas are often striking and would seem to traverse my contention. You send a man to Contrexéville, for instance, and he passes large quantities of uric acid while there, and he comes back feeling light as air. Far be it from me to deny the benefit that is often obtained at such places, I send too many away on errands of this kind to so belittle mine own honesty. But before accepting straight off the explanation that the uric acid is *extracted* as a matter of depuration from the blood or tissues, a philosophical inquiry must at least consider the possibility of other causes. Years ago I remember paying a visit with a friend to some aniline dye works, and there I saw that, amid abounding commercial prosperity, the manufacturer was overwhelmed with pitch. And here also it is possible—I pray that the magicians of hydrotherapy may forgive me for such a heresy,—it is possible that, like other by-products of commercial success, uric acid may be manufactured on the premises, so to speak, and that there are specimens of it that ought to be labeled "Made in France" or "Made in Germany." In the daily manipulation of many urines, year after year, I have often been struck by the sensitiveness that this fluid displays to the addition of foreign constituents. There is many a man, for instance, who notices that he is passing uric acid because he happens to micturate into some cold urine or perhaps passes urine of one specific gravity into urine of another specific gravity; a specimen of this kind in a nervous observant man might easily lead him to suppose that he was risking the formation of stone in the kidney or bladder and that it was necessary to undergo a course of treatment for it, but I am sure that it is passed in solution, and I am indebted to Dr. Luff's most interesting and instructive Goulstonian Lectures on the Chemistry and Pathology of Gout for what seems to me the probable explanation of the phenomenon. Dr. Bence Jones, he writes, was the first to show that the amorphous urate deposit yielded to water a soluble moiety consisting of true biurate and left a sediment consisting of pure uric acid.[1] Winter work gives one quite a different view of urines from that given by summer work. It is one of the small bothers of work in cold weather that materials crystallise out so much more readily and thus convey false impressions, and this both with and without reagents. It is one of the drawbacks of the ferro-cyanide test for albumin that the preliminary acidification with citric acid so often clouds the fluid with an amorphous deposit and which does not always readily clear with heat, as it is said it always does. I think that it is possible, too, that mucus in the urine has something to do with this sensitiveness or otherwise to reagents and I have always thought that Dr. W. M. Ord's observations upon the rôle of mucus in the formation of urinary calculi are of great clinical interest.

But to return to waters and their effect upon uric acid. I have often been struck, as many of you must have been, and amused besides, with the fact that the medical men at spas almost invariably say to their patients, "The good does not come at once, you may even be worse before you are better; you must await the 'bye-and-bye,' and you will require to come again for two or three years to get the full benefit of our waters." Yes, these gentlemen have the most canny way of eating their cake and having it. Nevertheless, what they say is true. We all know that it frequently happens that a man goes to waters to get rid of his uric acid and he has a bad attack of gout directly his course is over, or mayhap when it is half through. I have been told by those who have been at Contrexéville that they have passed, not uric acid but oxalates; some, as I have already noted, have passed phosphates, and it is also the fact that the first effect of the waters is to reduce one to a state of absolute limpness and enervation. It is most difficult to understand this if there be any real depuration. This one would suppose should start and go on progressively. But it is not so, many patients are at first much deranged in their digestion by the treatment, and are, I should say, in the very ideal condition for making and passing a good output of uric acid.

---

[1] The Pathology of Gout, p. 65.

Then, too, some of the uric acid that is passed is probably washed or dissolved out of the passages. There is nothing more common in the post-mortem room than to see the kidney studded over with minute deposits of uric acid, and I am firmly convinced—for I think I have seen evidence of it clinically—that free water-drinking performs an even more difficult task than that of flushing out sand from the passages, viz., that it softens and disintegrates small calculi. I daresay that we have some of us seen small calculi passed after this treatment has been perseveringly adopted, and I once made a post-mortem examination in a case that had been undergoing this treatment, and the stone was found soft and sabulous, so that it could be crushed to powder under the finger. To be fair, I suppose it is possible that the unbeliever might say that the stone was in course of formation, not of softening, but I think the probabilities were the other way. This point is surely worth insisting upon in these days of energetic surgery. Not long ago a friend of mine came to me with well-marked renal colic. I put him on the water cure and told him to drink it for some months, but he was a nervous, plucky, excitable fellow, and as his attacks of pain recurred he decided to be cut. He was cut and no stone was found, and three or four days after he passed his stone per vias naturales.

But although the human body is often astonishingly accommodating, it cannot be but that a sudden change such as the introduction of five or six pints of saline water, must necessitate some complicated adjustments in its arrangements, and there are likely to be other results in addition, and too often in place of, the mission on which we send it. Ah! there lies the whole crux of medicine, or of the treatment of disease, rather. These teeming kilns, each busy with its own work, although linked to each other in one whole, the body corporate, will each go its own way and our special purpose is too often dissipated in the doing.

There are, of course, other most important conditions to be considered in estimating the value of water proper—for instance, what a Turkish bath does, with the delicious sense of languor that follows it and the brightness and freshness that come after; this is often exactly reproduced by a course of waters. Then there is the change of scene, of climate, and of diet. These are very important factors, but they are on the surface, and I need not dwell on them. And while I am on the subject of water-drinking it may not be inapposite to say that the question of hard or soft water if taken freely, is probably not an unimportant matter to the standard of health. There is a common belief abroad, I think, that hard drinking waters are detrimental to health and I am very much inclined to take that view myself. But unfortunately it is one of those questions, like that of climate, which are exceedingly difficult to obtain precise facts about. Still, if it be true, as many think, and the history of goitre seems to prove, that there are dangers in the habitual use of hard waters, it at any rate may go to suggest that copious libations of any waters impregnated with saline products may possibly also lead to detrimental results from too indiscriminate use.

But I must be drawing to a close. In doing so, let me summarise a little, for I fear that my thoughts have tumbled out somewhat disjointedly. My contention is that uric acid is a common product that may well be considered as the ash resulting from the workings of our many-chambered kiln, and that the fault, if fault there be, lies not in the ash, or even in the coal from which it is produced, but in the driver, or in this case the driving power, that should regulate the process of combustion. And though this sounds vague, as indeed in the present state of our knowledge it is, it does not necessarily follow that it is any the less true. The uric acid passer invariably presents to you a problem to be unravelled, and each case a problem more or less distinct and separate from every other. In one case the cause may be the visceral sluggishness that is the common outcome of nervous exhaustion; in another, the hereditary condition, whatever it be, that determines gout, and which certainly works out its mission independently of any dietetic indiscretions, for how often we hear the lament from such, "Well, I never earned it." In another, it may be a great or sudden shock, a great anxiety, an exhausting attack of illness; in another some early defect of the kidney; in another case perhaps all we can say is that it appears to be the first indication of the growing old, and of the failure of the organism to accommodate itself sufficiently rapidly to various changes of its environment, whether they be climatic or dietetic or what not, which is one of the chief distinctions between healthy youth and age. These are the things that determine the verve of our several organs, and these, therefore, are the prime movers in the production of uric acid. No doubt all these things are wanting in precision and tangibility, but they are none the less the causes of disease. To wash out a mere chemical product might seem a much easier matter and what is called a good working hypothesis, but what about results? Well, there we shall no doubt agree to differ. For myself I cannot but think that had it not been for our eagerness to get hold of something to "treat," the uric acid theory that is dominant at the present day would never have become the fetish that it has.

One of the weaknesses of our profession is this, that we incline to do too much, and in so doing over-treat disease. It is our virtue rather than our fault, for if there be any vice from which as a profession we are free it is that of the mercenary spirit, and this in spite of a certain letter that appeared in the *Times* lately. But, as you all know, the public will have physic for every ailment. We are eager to cure disease as quickly as possible, and so we often come to look too anxiously upon what are hardly more than physiological deflexions. I have often thought that we might with advantage cull a leaf out of the book of clerical customs and from time to time go into "retreat" as they call it. We might then have time to pause in the treatment of detail and to take a broad survey, each of us, of the teachings of our own experience.

Do not you find, you my hearers who have come to middle age and passed it, that one of the chief pleasures of your position is that of having a firmer conviction of the self-righting power of the human body? Let it alone; give it time, rest, freedom, fresh air. It must be so. For I hear it said on all sides of the ripe and mellow go-aheads of but a few years ago, by their juniors the go-aheads of to day, how much less active they are than they were when they began to make their names. Yes; they now wait and watch. Alert still, but with a more chastened judgment that is well worth study. And surely this tells us that their experience has taught them to take an ampler view of the buoyancy and tenacity of life; that they have seen that many of their earlier efforts were petty interferences with greater power that tends almost inexhaustibly towards health, and "trusting the larger hope" they have shed off the immaturity of meddlesomeness.

A Clinical Lecture

UPON

INTERNAL DERANGEMENTS OF THE KNEE-JOINT (POPULARLY CALLED "SLIPPED CARTILAGE"), BASED UPON A SERIES OF 200 CASES.

Delivered at St. George's Hospital

BY WILLIAM H. BENNETT, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL; JOINT LECTURER ON SURGERY IN THE MEDICAL SCHOOL; MEMBER OF THE COURT OF EXAMINERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, &C.

GENTLEMEN,—Some of you probably recollect having seen me operate a few days since upon a patient in the Fitzwilliam Ward who was generally supposed to be suffering from the results of a displaced semilunar cartilage in the right knee. The operation, however, showed that the symptoms were not due to that cause but arose from an abnormal fold of synovial membrane connected with the ligamentum mucosum which from time to time became nipped between the bones. The occurrence of this case gives me the opportunity, for which I have been for some time waiting, to call your attention to the condition of the knee joint—for clinical purposes indifferently styled "internal derangement," "displaced semilunar cartilage," or "subluxation"—which is not only interesting in itself, since its comparatively common occurrence brings it under frequent observation in practice, but is also well worthy of that careful consideration which is especially desirable in conditions in which, from long familiarity, the respect which naturally attaches *to accepted traditional views leads to* their adoption at times without much critical inquiry. Some of the conclusions in respect to diagnosis and treatment to which I shall refer in the following lecture will, I fear, be found to differ from some of the views commonly held; they are, however, the outcome of the careful study of 200 consecutive cases.

ANALYSIS OF THE CASES.

The total number of cases in the series numbered 200 (182 males and 18 females); these included only such as presented the characteristic symptoms under discussion, all cases *which could be classified under the head of* "loose bodies" commonly so called being excluded. The ages of the patients varied from 13 to 62 years. The left knee was affected in 133 cases and the right in 57. The inner side of the knee was the seat of the symptoms in 155 cases and the outer side in 45 cases. 98 cases were seen after the first attack and 47 after the second; in the remainder the number of attacks occurring before the patient came under observation varied from three to 22. With the exception of 20 cases, which were too far advanced, all were at first treated by temporary rest, massage, and exercises; of these 112 were cured, 83 without the use of any support or other apparatus; in 39 temporary support was necessary for times varying from three months to one year. In no case in which the rest and massage treatment was commenced after the third attack was sufficient improvement effected to enable the patient in the absence of opera*tion to entirely dispense with the use of support of some* kind, but in a certain proportion of these the support was only used as a precaution under special circumstances. The cases in which a support was used permanently (being worn either continuously during the day only or at various intervals) amounted to 58; of these, the treatment commenced after the first attack in 25, after the second attack in 18, and after three or more attacks in 15. Three patients declined treatment altogether. Operation was performed in 27 cases (all males); of these, the semilunar cartilage was at fault in 15 only; of the remaining 12 the causes of the trouble were small pedunculated bodies in four instances and abnormal folds of synovial membrane springing from or near the ligamentum mucosum in eight. In the 15 cases submitted to operation in which the semilunar cartilage was involved the left knee was affected in 12; of the other operation cases seven occurred in the left knee and five in the right.

It is hardly needful to say that these cases do not represent my whole experience of this condition; I have, however, thought it well to confine my observations to this series as the cases coming under my notice prior to them were not observed with sufficient care to justify any definite conclusions, although the impressions they led me to form were practically the same as those resulting from the consideration of the series under notice now.

THE SYMPTOMS AND THEIR CAUSES.

The train of symptoms usually recognised as indicative of the lesion are precise enough—*viz.*, *sudden pain with or* without a sensation of something having slipped out of place in the joint, complete fixation or limitation of the power of extension of the leg upon the thigh at any angle between complete extension and a point half way to semiflexion, followed by effusion into the joint with tenderness over one or other semilunar cartilage. These symptoms may occur apparently spontaneously during some normal movement or may result from a violent wrench or blow; speaking generally, rotation movement of the leg upon the thigh is a prominent factor in their causation. Relief may follow almost immediately from spontaneous reduction of the displaced or nipped structure or it may be effected by reduction by manipulation.

In some cases, principally the slighter ones, which for reasons to be stated are of extreme interest, manipulation not only fails to give relief but may cause an increase of the symptoms. It is not infrequently stated that in marked cases of displacement of the semilunar cartilage the structure can be felt upon palpation, but I venture to think that these cases must be very few in number; it is often possible to feel some fulness along the line of the cartilage, but I believe it is, as a rule, merely the swelling from blood extravasation with or without inflammatory exudation, and I am sure that the existence of thickenings of this kind is no certain sign of displacement of the cartilage. In fact, so far as I know, the only *positive sign of the lesion being a displaced cartilage* is the occurrence of a deficiency, upon comparing opposite limbs, felt above the head of the tibia on the affected side in consequence of displacement of the cartilage freely inwards. Projecting thickenings are no evidence of cartilage displacement, since any loose body fixed between the bones may give rise to exactly the same abnormality in outline. It is a matter of common knowledge that although the train of symptoms in these cases is so precise and clear, the causes to which they are due are by no means always the same and may be classified as follows: (1) displacement of a semilunar cartilage; (2) the nipping of folds or threads of synovial membranes between the bone ends; and (3) loose or pedunculated bodies in the joint. To these three commonly recognised causes I venture to add (4) bruising of the peripheral edge of a semilunar cartilage and its attachments without displacement or necessarily loosening, the immediate result of the lesion being a local effusion of blood (subsequently reinforced by a certain amount of inflammatory exudation) a portion of which insinuating itself between the bone ends acts as a foreign body. To this condition I have heard no allusion made nor have I met with any mention of it in surgical literature. It is, however, I believe, the cause of the train of symptoms in the majority of the milder cases of so called "slipped cartilage." It is quite curable by proper treatment, whilst if neglected or improperly managed at first, it leads to some of the most intractable cases of the graver sort.

In order to make my reasons for this belief clear it is necessary to refer to the following elementary points. The essential symptom in all these cases is, as everybody knows, the fixation or at all events limitation in the movement of the joint resulting from the existence of foreign material between the bone ends. If the foreign substance be a portion of a semilunar cartilage, loose body, or fold of synovial membrane the symptoms are very pronounced, but they disappear at once after reduction has been effected, whether the reduction occurs spontaneously or is brought about by manipulation, the movements of the joint being at once recovered. The only positive evidence of successful reduction lies in the ability to extend the leg upon the thigh without resistance as completely as in the sound limb; anything short of this is held to show that some mechanical obstacle in the way of foreign material between the bones still exists. Unless my experience is exceptional it must have been noticed by others in the majority of cases of the milder sort in which the limitation of movement is only slight that although the symptoms are precise enough the limitation in the extension of the leg cannot be rectified by manipulation, however carefully it may be carried out; "reduction" of the "displaced" material cannot, in fact, be accomplished. Not only does the inability on the part of the patient to completely extend the limb remain unchanged by the manipulation, but it will be found that even under an anæsthetic it is impossible to completely straighten the limb. It is true that if the patient whilst anæsthetised be laid on his back the limb can be put practically straight if firm backward pressure be made *upon the front of the knee* but *upon the removal of the* pressure the knee immediately springs forward, leaving the limb bent to the same degree as before it was straightened in the manner indicated. The failure of attempts at reduction in these cases is due not necessarily to any want of skill in the manipulation but to the fact that there is nothing present which in the ordinary sense is reducible. In spite of the apparent intractability of these cases at first they invariably recover completely if properly treated and do not recur. The important point to note in their progress is this: the recovery of complete extension is *gradual*, never sudden as is the case when a foreign body has been withdrawn from between the bones. *In these* cases the symptoms arise I believe, from the swelling due to bruising and laceration about the peripheral margin of the semilunars and their attachments without displacement, the gradual recovery of free movement being due to the slow absorption of the effused products. The gradual way in which the normal state is regained is in itself enough to negative the existence of anything like a foreign body in the ordinary sense of the term, between the bones, and the nature of the treatment by which recovery is brought about, added to the absence of any tendency to recurrence in properly managed cases is strongly corroborative of this contention. Additional evidence of a very positive sort is afforded by two of the cases treated by operation in the series now under consideration; these two cases were for practical purposes alike; it is therefore sufficient for my present object to give the details of only one of them.

A soldier, about 32 years old, after a wrench of the left knee, suffered from the usual train of symptoms associated with "slipped cartilage"—i e, sudden pain, tenderness over the internal semilunar cartilage, and inability to straighten the limb completely at the knee. Attempts were made by an onlooker to "put the knee in," but without success. The patient, however, continued to get about with a partially stiff limb, and shortly afterwards, no proper treatment having been adopted, he was ordered on active service. With the knee in the condition indicated he with difficulty got through a campaign of some months' duration; from time to time after some strain or injury an acute sudden attack of pain, followed by effusion into the joint, occurred. I saw the patient about six months after the original injury; during the whole of this time the leg had never been completely extended upon the thigh. There was slight effusion into the knee with some increase of local heat; the knee was slightly flexed and could not be extended either by the patient or by passive movement. Over the middle of the internal semilunar cartilage was a spot of acute tenderness; a little fulness was also distinctly felt. From this tender spot the acute pain which followed upon any strain or other injury always started. After the treatment which I shall presently describe the knee had nearly regained by degrees its natural state, extension being almost complete, when unfortunately another strain reproduced the old condition. Subsequent attacks of the same kind followed and it was evident that unless the abnormal state could be cured by operation service in the army must be abandoned. I therefore operated with the usual precautions. The parts about the base of the semilunar cartilage inside the capsule of the joint over the tender area were swollen and infiltrated with blood (some of long standing) and exudation products. The cartilage itself was not detached and clearly could never have been displaced. Before removing the affected parts an attempt was made to straighten the limb, the capsule of course being freely open, without success. After the removal of the swollen tissues, including the portion of cartilage involved, the limb immediately fell into a perfectly straight position. A portion of the swollen mass which could be seen lying between the bones at the posterior part consisted of partly organised old blood-clot. The cartilage itself was hardly recognisable at first in the centre of the mass removed, as it had entirely lost its ordinary aspect and resembled more than anything else, both in appearance and to the touch, a piece of sodden felt; in front and behind this the cartilage differed but little from its usual anatomical characteristics. Creeping over the articular cartilage of the internal condyle for a distance of at least half an inch was a delicate layer of pink granulation tissue beneath which the cartilage was eaten away. From the general aspect of the case it was manifest that the condition, if left to itself, must have developed sooner or later into pulpy disease of the knee-joint. The altered cartilage having been removed and the bones cleared of old blood-clot and exudation tissue the wound was closed in the usual way. The progress of the case was naturally tedious and altogether caused me more anxiety than any other case of the same kind with which I have up to the present time had to deal; the final result was good and the patient rejoined his regiment in about four months.

In the other case, less advanced than the one just detailed, the condition of the parts and the appearance of the cartilage were precisely the same.

In two other cases in which a displaced semilunar cartilage had been long neglected the structure presented the same sodden, felt-like appearance. This felt like condition seen in some of these cases is of considerable interest, as it shows without doubt, I suppose, that the cartilage must either have been completely crushed at the time of injury, had become changed in consequence of subsequent inflammatory processes, or had become altered in consequence of constant grinding pressure to which it had been subjected. Of this peculiar change in the semilunar cartilage I find no mention in the authorities I have been able to consult, but I am informed by an eminent surgeon that he has met with cases of the kind. The recognition of this bruising and laceration about the semilunar cartilage without displacement as a cause of the symptoms commonly associated with "slipped cartilage" is of considerable moment in the treatment of such cases, as will presently be seen.

TREATMENT.

This may be conveniently considered under three heads: (1) the treatment by temporary rest, massage, and exercise; (2) the treatment by the use of apparatus; and (3) the operative treatment.

1. *The treatment by temporary rest, massage, and exercise.*—The views of surgeons with regard to the best method of treating these cases naturally differ. In the present lecture I propose merely to give the details of the measures which in my hands have proved the most successful. The first indication obviously in every case is the replacement of the structure apparently dislocated, if reduction has not already been effected either spontaneously or by manipulation prior to the patient coming under observation. The desirability of using an anæsthetic in attempts at reduction must depend partly upon the nature of the case and partly about the disposition of the individual concerned. The actual mode of procedure in attempting reduction it is superfluous to describe here. In exaggerated cases—i e., those in which there is complete fixation or great limitation of extension movement—reduction must be effected by repeated efforts if a single attempt fails; in the slight cases (those which I venture to classify as bruised or lacerated cartilage and attachments) it will be found that the power of complete extension cannot be suddenly restored by any manipulations. In such cases, a thorough attempt at reduction, if need be under an anæsthetic, having been made without restoring the complete extension movement at the knee-joint, no repetition of the attempt should be made since there is nothing to replace. The failure to appreciate this fact, resulting in repeated futile attempts at replacing the structure which is supposed to be displaced, has been the cause of some of the worst cases of traumatic arthritis of the knee-joint with which I have had to deal. The immediate treatment of all cases, whether they are those in which movement has been restored spontaneously or by manipulation, or whether they be of the kind in which some slight flexion exists in spite of attempts at reduction, is complete temporary rest by fixation of the joint on a light splint, a compress of warm water, or, as I prefer, since it is more soothing, one of hot lotio plumbi cum opio, being kept continually applied. The period during which this rest is maintained varies from four days to a week, the time, in fact, which is usually occupied in getting rid of the effusion into the joint. The less the joint is subjected to movement until all effusion has disappeared the better is the chance of a perfect result finally. I am certain from my own personal experience and from what I see and hear of the results of the practice of others that nothing militates against a successful end in these cases so much as the use of exercises, passive or in the gymnasium, immediately after the injury; it is, in fact, in my opinion, quite the worst practice that can be adopted, since the commencement of exercises immediately as is recommended by some, is, I have no doubt, at least as bad as the opposite extreme in which a limb may be crippled by being kept at rest too long.

Although no movements of the joint should be commenced until all effusion has gone massage of muscles and joint *without movement* cannot be commenced too soon; not only does the early massage expedite the disappearance of the fluid more than any other means, but it seems to check, if not to altogether prevent, the rapid muscle waste, and, most important of all, it greatly obviates *the tendency to flaccidity of the capsule of the joint which is such a fruitful cause of failure in these cases.* Nothing is more striking, I think, than the rapidity with which the muscles of the thigh and, to a less degree, those of the leg waste if left to themselves in this injury. In my cases, therefore, from the first during the temporary rest the limb is subjected to thorough massage without knee movement daily and if the circumstances admit twice a day. Upon the disappearance of the effusion, which in well-managed cases is rarely later than a week from the time of the injury, exercise by passive movement is commenced, *care being taken that no rotatory motion is imparted to the* *leg*—the avoidance of rotation is the essential point in these early movements; in the gymnastic treatment this cannot be with certainty achieved. The rotation movements which are inevitable in the voluntary exercises commonly prescribed directly bring about a looseness of the cartilage in the cases which originally are merely bruises or lacerations of attachments only, and in those which originally were displacements they tend to produce recurrence of the condition more certainly than any other means. It would be easy to give many examples in illustration of this point, but the one which follows will suffice.

A soldier, aged 42 years, had an undoubted displacement of the left internal semilunar cartilage; this was replaced soon afterwards by the practitioner who was at first consulted and the ordinary exercises of the gymnasium were at once prescribed. At the end of a week the displacement recurred; the pain was intense, complete extension being impossible; reduction was attempted but apparently without success, as no change in the condition of the limb followed. The exercises were continued and as much walking as possible was recommended. Six weeks later I saw the patient, the leg was then considerably flexed and could not be extended by manipulation, the knee was distended and the pain on walking was acute. Rest for a fortnight with massage without exercise removed the fluid and reduction occurred spontaneously whilst turning in bed. Recurrent attacks followed and ultimately I removed the portion of the semilunar cartilage concerned. Not more than half an inch of the anterior end was detached and I am strongly of opinion that if the case had been treated upon the lines which I recommend no operation would have been necessary. The object of the temporary fixation and massage is first of all to remove the fluid and secondly to allow the loose portion of the cartilage to fall back and adhere in its normal site which, with the help of the surrounding inflammation which almost always follows to some extent, it will generally do. The passive movement without rotation, whilst it does not disturb in any way the process of refixation, prevents any troublesome adhesion in the joint itself.

It is interesting, perhaps, to mention here with reference to what has just been said about the effect of inflammation in the refixation of a loosened cartilage that, so far as my experience goes, the cases in which the inflammation following immediately upon the injury is somewhat acute show less tendency to recurrence of symptoms, when the condition is adequately treated, than those in which the immediate inflammation is very slight or non-existent, which, if my view of what occurs is correct, is precisely what would be expected. At the end of a fortnight pedal exercises may be freely used, the massage being continued, and at the end of three weeks from the date of injury the patient, who has up till then been walking with a "stiff leg," begins ordinary walking exercise. The time during which the massage must be continued varies in different cases from three weeks to six months or possibly more. The time for its cessation is determined by the condition of the thigh muscles and of the *capsule of the joint*. Speaking generally, it may be said that *in no case* can it be considered safe to dispense with the treatment if the thigh muscles remain wasted or if the capsule is lax, the latter condition, which is practically dependent on the former, being the more important, as the lateral movement or "wobbling" of the joint which is associated with it is directly conducive to recurrence of the trouble in the articulation.

The importance of restoring the proper tone or tension of the capsule of the knee-joint in these cases is, I believe, not sufficiently appreciated, nor do I think the means of effecting this end are altogether a matter of common knowledge. It is too commonly known, I suppose, to need emphasis here that the normal tension or "tone" in the capsule of the healthy knee is greatly dependent upon the muscles in the thigh proper which send expansions to it, notably the quadriceps extensor. A factor, however, of prime importance in this matter is one which, judging from the way in which the treatment of these cases is frequently conducted, is not always held in sufficient esteem—I mean the ilio-tibial band, the elastic tension of which is upheld by the gluteus maximus and the tensor fasciæ femoris. It will be found in the majority of, if not in all, cases like those now under discussion, when the knee capsule is very lax and the lateral movements of the knee are excessive, that there is marked wasting of these two muscles. Although much attention is generally paid to the wasting of the quadriceps extensor and to attempts at the restoration of its normal condition I do not remember having seen attention called to the wasting of the muscles connected with the ilio-tibial band. The practical importance of this point to which I particularly wish to direct attention is this. In attempting the restoration of the normal tension of the knee capsule by massage and exercises the treatment must not be limited to the obviously wasted muscles in the thigh—the quadriceps extensor, for example—but should be applied with equal vigour to the muscles connected with the ilio-tibial band, the gluteus maximus, and the tensor fasciæ femoris. The method which I have given in detail is that which I have come to believe to be best for the management of the cases now in view if a cure in the true sense is aimed at. I am well aware that in many instances the method must be too expensive and possibly from the patient's point of view too tedious to be practicable. Such cases should be managed with as little modification of the plan described as circumstances allow, the essential points of the immediate treatment—viz., temporary rest for the joint and avoidance of rotation movement—being especially borne in mind.

2. *Treatment by the use of apparatus.*—On this head little requires to be said. No support or apparatus of any kind should be employed unless absolutely unavoidable; moreover, the use of instrumental support of any kind in the case of a patient whose treatment has been commenced immediately after the receipt of the original injury must, excepting in a few special circumstances, be held to be sure evidence of the failure of the treatment primarily adopted. It cannot be too strongly emphasised that the use of artificial supports always tends to render permanent the wasting of the thigh muscles to an extent which varies in degree with the kind of instrument employed. The cases in which the use of supports is justifiable are limited as follows: (1) cases in which for unavoidable reasons the rational treatment cannot be carried out; (2) cases in which the rational treatment fails to restore the normal tension of the knee capsule or those in which abnormal lateral mobility remains to any marked extent in spite of the treatment; and (3) cases in which recurrent attacks of semilunar displacement have occurred frequently, operation having been for some reason rejected. When the symptoms point with reasonable certainty to the existence of a loose body other than a displaced cartilage the use of a support is obviously useless, operation being the only method which offers a prospect of relief. In the event of the use of a support being, for sufficient reasons, decided upon it is of importance that it should be constructed on proper principles; all the ordinary "knee caps," whether of elastic or inelastic material, are to be avoided, as, whilst they do not in any sense provide the means for acquiring the desired end, they tend more than any other contrivance to increase and perpetuate the wasting of the thigh muscles.

The object to be attained by artificial support is the prevention of rotation of the leg at the knee—to reduce, in fact, as much as possible the knee to the condition of a true hinge; in the manufacture of these instruments this salient point is the principal factor to be kept in view. It is too often *thought that a truss or pad may be made, by the pressure* of which a semilunar cartilage can be kept in its proper site. A moment's consideration will show that this is impracticable, especially in the face of the fact that in these cases of loosened semilunar cartilage the displacement is generally inwards towards the articulation—a direction upon which an external pad could by no amount of ingenuity be made to bear. All that can be accomplished by properly devised instruments is the gripping of the head of the tibia with a view to the prevention of rotation, and I am acquainted only with two appliances which reasonably effect this purpose, one being complicated and expensive, whilst the other is comparatively simple and inexpensive. So far as the effect is concerned I do not know that the one is better than the other. The small spring "trusses" sometimes supplied are entirely useless.

THE OPERATIVE TREATMENT.

With regard to the propriety of the removal of displaced or loosened semilunar cartilages there appears even now to be some divergence of opinion, for whilst some surgeons, the majority I suppose, think removal the only practical plan of treatment in certain cases, others adopt the opposite extreme and incline to reject the operation altogether; indeed, some appear to think it an unjustifiable mutilation. For my own part I believe that no operative measures in these cases short of removal of the offending cartilage is efficient and there is no doubt that if necessary the cartilage can be removed with advantage; indeed, in some cases its removal affords the only possible means of providing a workable joint, and I have certainly seen no reason to believe that any defect in result after operation arises from the mere absence of the cartilage. At the same time I am of opinion that the percentage of cases in which operative measures of any kind are necessary in cases presenting the recognised train of symptoms should be very small indeed if the original treatment has been properly managed. Under any circumstances, I am sure that operative measures should, speaking generally, be postponed until all other treatment has failed to satisfy the patient. If the original treatment is rationally conducted I further believe that operations in these cases would be found to be limited for the most part to the removal of pedunculated bodies and synovial folds. The semilunar cartilages would rarely require operative interference.

The fact that it is practically impossible, excepting in those unusual instances in which the cartilage can be felt to be absent from its normal site, to determine what is the real cause of the trouble in these cases without opening the joint renders exploratory operations in intractable cases obviously desirable, but having regard to the large percentage of cases which are curable without operation the explorations should in my opinion be reserved for (1) cases in which non operative measures have conclusively failed to cure or sufficiently modify the symptoms to satisfy the patient; (2) cases in which general flaccidity of the joint, as shown by an abnormal amount of lateral movement upon manipulation, is in excess of the other symptoms. (I have already indicated the important part which this flaccidity plays in the ultimate result of the treatment of these cases and the strongest indication for exploratory operation is afforded, in my opinion, by progressive looseness of the joint generally; it is at the same time well to note that these loose joints, especially if the lesion involves the semilunar cartilage, are those in which the tendency to defective results is strongest); (3) cases of expediency in which an early attempt at relief is urgently called for by special circumstances, such, for example, as may be the case of a soldier or any person in the public services to whom the persistence of a physical defect may entail the relinquishing of his career, or in the case of gymnasts and the like; and (4) grossly neglected cases in which from long-continued inflammation the joint has assumed the aspect of pulpy disease. Such cases are, however, rare and, indeed, in the true sense are outside the category both clinically and from the operative aspect of those now being discussed.

The reasons for restricting operative treatment to such a comparatively small number of cases are the following: 1. The vast majority of these cases are, I believe, curable by the means already indicated, and of the remainder many, although not curable in the true sense, can with or without suitable apparatus be made of so little inconvenience that the majority of patients are too well content with their condition to submit to the inconvenience, accidental risk, and expense of an operation the result of which may, after all, be disappointing. 2. The operative measures necessary for dealing with these cases when the semilunar cartilage is the structure at fault cannot be regarded as entirely free from risk. It is, I believe, a fact that although opening the knee-joint for the removal of loose bodies or synovial folds is rarely, if ever, followed by anything but uneventful recovery in competent hands the removal of a semilunar cartilage is by no means so free from subsequent trouble as is generally imagined or as would be concluded from a perusal of recorded cases, and I cannot but believe that if the results of all the cases operated upon in London in the course, say, of any five consecutive years could be forthcoming the general estimate of this operation would be lower than it at present is. Although up to the present time I have had no disaster after opening the knee-joint with the exception of one instance in which direct septic infection occurred from accidental causes entirely beyond my control in a case not included in the series now under consideration because it was of a different kind, I must admit that two of the present cases were the cause of much anxiety. The temperature charts of these cases are appended; no suppuration occurred and no active measures were necessary, but it would be idle to deny that during the periods covered by the charts these patients were in a somewhat critical condition so far as the utility of the joint (and perhaps the integrity of the limb) was concerned. It is at the same time noteworthy that the results of these cases ultimately proved to be the most perfect of the series of those subjected to operation. Under any circumstances, however, the risks are, of course, comparatively small and mainly accidental, but they are, I submit, sufficient to merit consideration in the discussion of the *pros* and *cons* of this operation, which I venture to think is occasionally too lightly undertaken. 3. The results of operation are not always perfect. Apart from cases in which failure is complete—viz., those which end in a completely stiff joint or possibly the loss of the limb—there is undoubtedly a certain percentage of failures from (1) recurrence of the symptoms and (2) partial stiffness of the joint. Of the general proportion of these failures it is of course impossible to acquire accurate knowledge; but in my series of *removal* of the semilunar cartilage recurrent symptoms occurred in one and some slight limitation of movement in one, whilst in the two cases in which the cartilage was *fixed by sutures* the symptoms recurred in less than a year from the time of operation.

Fig. 1.

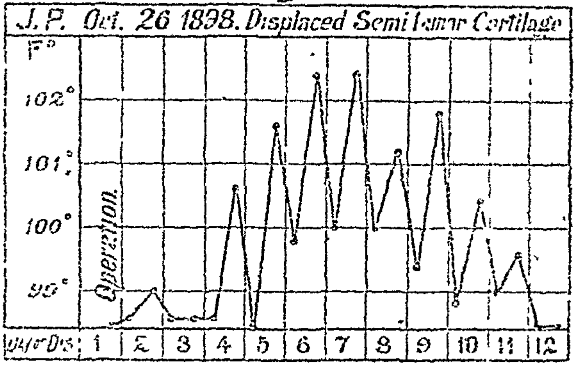

Fig. 2

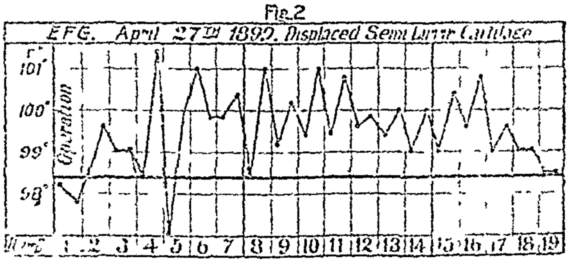

It is conceivable that it may be submitted, and indeed I have heard it suggested, that in exaggerated cases even if a stiff limb results after operation the patient's condition is not only no worse but really better than before; admitting, for sake of argument, that this may be so in some cases it cannot be urged that the result is anything but failure in the case of an operation performed with the express object of providing a normal joint. To deliberately produce by operation a stiff limb may in some of the cases be proper enough under certain circumstances, but to regard a stiff limb as a satisfactory result of an operation performed with the sole object of giving a freely moveable joint is hardly rational.

With regard to the method of operating I have found the vertical incision (converted, if necessary, into an L-shape) all that is requisite to give access to the part and I confess that I am at a loss to understand the reason for the extensive transverse incision, including of course the division of the patella, which is now advocated by some. The operation performed in this way seems to be unnecessarily severe and must, *cæteris paribus*, tend to interfere more with the subsequent perfection of the joint than the simple longitudinal incision could possibly do. Moreover, so far as I have seen, no very extensive exposure of the joint is necessary in these cases; the localised symptoms indicate very clearly the seat of the trouble which is readily accessible through a moderate incision. In the case in my series in which after removal of the offending structure recurrent symptoms occurred it was suggested that the recurrence was due to some fold having escaped notice in consequence of the exposure of the joint cavity having been insufficient, but at the second operation it was clear that this was not the case, as the cause of the recurrent symptoms was a growth of tissue into the joint from the line of the division of the synovial membrane at the previous operation

There can, I think, be no doubt that the success of the operation depends more upon the management of the case before and after the treatment than upon any special method of operating The following plan of management will, I believe, be found to produce the best results, it was followed in all the cases now mentioned excepting that in which some limitation of movement occurred The patient is kept in bed for a week prior to the operation, daily massage without passive movement is used, and no thought of operation is entertained until all fluid in the joint has disappeared To operate in the presence of fluid in the joint is, I am sure, quite unjustifiable After the operation, unless pain or other unforeseen conditions are contra indicative, massage of the limb generally above and below the knee is commenced, the dressings, of course being left undisturbed Gentle passive movement of the patella in order to prevent it becoming in any way fixed, one of the most important points in the subsequent progress of the case, is commenced not later than on the fourth day the outer dressings being if necessary removed daily for this purpose At the end of a week passive movement of the knee is generally commenced and can as a rule in ordinary cases be carried out by the patient the splint being removed for a short time daily To the constant use of skilled muscle massage I attach great importance for reasons already discussed in connexion with flaccidity of the joint capsule, upon the presence or absence of which depends to a very large extent the failure or success of the case In connexion with the progress of the cases after operation, when the semilunar cartilage itself is dealt with, an interesting point is afforded by the variability in the course of the cases during the first week which in the majority is unattended by pain or discomfort of any kind, there being neither effusion nor other objectionable development On the other hand, pain with or without effusion in some cases is intense the temperature at the same time perhaps rising to a serious degree I have rarely, I think, seen more severe pain than that suffered by one of my patients although the joint did not become tense and the temperature did not reach a higher point than 99 2° F In two other cases the pain was extreme indeed almost intolerable; in each of these some tension of the joint arose, the effusion in each commencing at some time during the third day The bulk of this pain seemed to be due to, or at all events to be greatly increased by, muscle spasm or cramp both in the leg and thigh which could only be relieved by gentle smooth massage, during which the patient would often fall asleep It is perhaps worthy of note that the cases in which these apparently unfavourable symptoms developed produced ultimately the most perfect results which I have had, the joints in all being finally perfectly normal in every sense of the word This effusion coming on several days after the opening of the joint must, I assume, be due to inflammation, and I am inclined to think that a certain amount of inflammation, provided, of course, that it subsides before harm is done is advantageous, as it is, I submit, not unlikely that the inflammatory process may tend to fix any loose parts in the operation area which in the absence of inflammation may by reason of their looseness give rise to recurrent symptoms In this connexion it is significant that of all my cases the one which made the most rapid and perfect progress so far as absence of discomfort was concerned was that in which recurrent symptoms followed upon the removal of the anterior two thirds of the left semilunar cartilage

In conclusion it is fair to allow that, having regard to the admitted comparatively slight risk of these operations and the impossibility of determining with certainty the conditions at fault in the majority of these cases without opening the joint, it may be with reason submitted that a more rational plan than reserving the operation as a last resource or at all events postponing it until other means have failed would be to first perform the exploratory operation and then proceed with the treatment indicated by the circumstances revealed. My objections in this connexion are mainly two In the first place, I do not think that the measures at our disposal are sufficiently certain to admit of the performance of these operations with entire impunity, and in the second place I cannot admit that the possibility (thanks to the antiseptic system) of operating without risk other than that which may be regarded as accidental is in itself any justification for the performance of operations in cases in which there is certainly a good chance in the majority of attaining the end in view without operative interference This latter aspect of the question is, I believe worthy of special consideration at the present time when I cannot help feeling that the tendency to reduce the practice of surgery to what is little more than a mere handicraft is somewhat too strong

THE HISTOLOGY AND PREVENTION OF BLACKWATER FEVER

(With Coloured Illustration)

By W H CROSSE, M R C S Eng , L F P S Glasg ,

CONSULTING MEDICAL OFFICER TO THE ROYAL NIGER COMPANY

The disease called blackwater fever has caused, and is still causing such serious loss of life in tropical West and East Africa that any information upon the subject cannot fail to be of interest especially at the present time when the countries in these regions are being rapidly opened up Blackwater fever or hæmoglobinuric fever I have previously defined[1] as "a febrile disease of malarial type characterised by hæmoglobinuria jaundice and vomiting" As bearing upon the histology of this disease a description of a case which came under my notice, and which I was enabled to examine post mortem, may perhaps add something to our knowledge

A man aged 26 years had resided in the Niger territories for 16 months, this being the first time he had been out of England He came of a neurotic stock but had been passed as sound in England His work, that of a clerk, necessitated a considerable amount of exposure, both during the heat of the day and the chill of the evening. He was very "slack" in his care of himself—that is, he often went out into the sun without using a sufficient protection for his head, and if his clothes became wet either through free perspiration or actual wetting he often neglected to change them at once He was a heavy smoker, but in other things was quite moderate As the result of his "slackness" he frequently took chills, and as his work lay altogether on the lower 300 miles of the Niger territory, where mosquitoes abound, he was doubtless frequently bitten by them He took quinine only when he felt that he needed it and not at all regularly. About six weeks after his arrival in the territories he had his first attack of malaria and from that time he had an attack about every month Some of these attacks were probably relapses rather than fresh infections For two or three days before he was laid up with what proved to be his last illness he had been cold, but he kept to his work. On the day following that on which he really laid up he complained of nausea There was much fever and chilliness, his skin was noticed to be yellow, and his urine was "porter like He was put on board a launch and was brought a day s journey down the river to me When I saw him he was deeply jaundiced, his urine was hæmoglobinous, and he was suffering from persistent vomiting, the vomit being markedly green in colour The urine rapidly diminished in quantity and the patient died on the sixth day after the hæmoglobinuria first set in , the vomiting persisted to the end, and was accompanied by a most distressing hiccough and by some dyspnœa and pain in the limbs Pieces of the various organs were obtained, and these have been cut and stained by my friend, Dr T G Stevens, to whom I am indebted both for the descriptions and for the illustrations

Histological Examination of Organs

Kidney —Sections were cut in paraffin, stained with Ehrlich s hæmatoxylon and counterstained with "Licht

---

[1] Blackwater Fever Transactions of the Epidemiological Society 1898 99

Grün." The sections do not show any very advanced change; there is, however, some necrosis of the epithelium of the convoluted tubules and Henle's tubes. The necrosis is superficial only, filling the lumen with granular débris. The nuclei of the necrotic cells do not stain well, they seem to be fewer in number, and are breaking up. There is no interstitial change and the glomeruli are unaffected. There are no hæmorrhages or deposition of pigment. The changes described are consistent with an early parenchymatous nephritis.

Liver.—Sections were cut in paraffin, stained with Ehrlich's hæmatoxylin and counterstained with "Licht Grün." The sections show very conspicuously the pigmentation of the hepatic cells. The pigment is distributed fairly evenly in all parts of the lobules. The granules of pigment vary somewhat in colour from pale yellow to brown or almost black. The pigment is contained in the general protoplasm of the hepatic cells, not in the nuclei. In the capillaries are to be seen endothelial cells also containing similar pigment and pigmented leucocytes. In addition to this pigmentation the capillaries between the hepatic cells are dilated throughout the section. The capsule of the organ is thickened. There is no increase of connective tissue in the substance of the liver.

Spleen.—Sections were cut in paraffin and stained with Ehrlich's hæmatoxylon. The sections show a widely spread and advanced degree of fibrosis. The capsule and trabeculæ are much thickened and fibrous and devoid of nuclei. The stroma of the pulp tissue is considerably increased. Scattered throughout the section are seen masses of pigment of varying size and colour, the colour being bright yellow or brown to almost black. The pigment is apparently in leucocytes and also lies free among the cells. The larger masses of pigment are found in the Malpighian bodies. The smaller vessels have a very marked thickening of their sheaths; the walls are degenerate and have very few nuclei; the lumen is much reduced or even obliterated.

Cerebrum.—Sections were cut in paraffin and stained with borax methylene blue. The sections show no definite changes; there is no deposition of pigment. The vessels appear to be normal. Owing to the long maceration in spirit which probably on account of climatic conditions on the Niger was not absolute, the capillaries of the cerebrum have no complete blood corpuscles in them, but only some granular débris. Under these circumstances it is, of course, impossible to demonstrate the malarial parasite which in these cases is said to be found in the capillaries of the brain. About a dozen sections in all were examined, but no satisfactory corpuscles were found.

It will be seen that so far as one can see the above sections show nothing that cannot be found in the tissues of a patient who has had several attacks of malaria. It would appear, however, that it is possible for a patient to have had malaria many times and yet show no pigmentation of any organ except the spleen. In two of the cases of blackwater fever published by Koch[2] he states that both patients had repeatedly suffered from fever which reacted to quinine; in one only the spleen showed pigment granules and in the other he states: "The deposit of pigment in the endothelium of the spleen and liver, so characteristic of malarial disease, was likewise lacking."

Before discussing the prevention of this disease it will be necessary to say—even at the expense of repetition—something concerning its cause. Last December Mr. W. C. C Pakes and I[3] suggested that blackwater fever bore to malarial fever a similar relation to that borne by hyperpyrexia to rheumatic fever. I should like in the first place to examine Koch's cases. 1. It is strange that, although Koch inquires, "Therefore how can one still assert that blackwater fever is caused by malaria parasites?" in all his cases which have so far been published, in the *Journal of Tropical Medicine* there is a definite history of previous malarial attacks. 2. In all the cases except No. 7, where the patient had taken quinine, he took it because he felt unwell. In Case 7, although the patient felt well on the morning upon which he took the quinine, he had had intermittent fever for the preceding few days. 3. The cases of hæmoglobinuria published by Tomaselli which were caused by quinine did not, so far as I can make out, resemble blackwater fever in any other respect than in that of the presence of hæmoglobinuria. 4. If blackwater fever is, as Koch maintains it is, an intoxication by quinine no case of the disease could occur unless the patient had taken quinine. But I have already published a case[4] where the patient had no quinine until he had developed well-marked blackwater fever. 5. Koch concludes that "the lack of parasites in more than half of all cases, and the omission of the relapses would alone suffice to prove that blackwater fever itself cannot be malaria, but that it is pretty frequently associated with malaria." The lack of parasites during and subsequent to an attack of blackwater fever is of course well known, but I cannot see that any of these cases were examined for parasites *before* the attack of blackwater fever. The absence of relapses is to my mind very inconclusive since he makes no mention of the time during which they were under observation or of their surroundings during that time. It is not at all rare to find that a patient may be quite free from relapses of malaria for many months—in fact, there seems to be no doubt that some cases undergo a spontaneous cure. In short, I see no reason yet to modify the view which we suggested—that it is a complication of malaria. I quite agree to describe the condition as an intoxication, but of malarial origin.

The following case which I have recently had under my care is of great interest chiefly from the reason that I saw the patient before the attack of blackwater fever commenced.

A man, aged 22 years, had been to West Africa twice; during his first stay he had an attack of blackwater fever and he was quite recently invalided home for the same complaint. He arrived home in bitter weather and came to see me as he had felt unwell and chilly for two or three days, but during this time he did not lie up. I took several specimens of his blood and examined them. Some of the specimens were stained with carbol-thionin blue and others with eosin methylene blue. The hæmatozoa, which were fairly numerous were seen to be in two stages. All but two were about one-third of the diameter of the red disc in size, circular, oval, or in the shape of a signet ring and without pigment. The discs were not enlarged and the portions not occupied by the parasite took the eosin stain well. The two above mentioned were larger, occupying about two-thirds of the area of the disc (which, however, was not enlarged), with irregular edges and with several granules of pigment scattered throughout the hæmatozoon. On the same evening he went to a theatre, but feeling very ill went home, where upon his arrival he vomited. In consequence of finding parasites in his blood nine grains of the hydrobromate of quinine were taken by him after his return from the theatre. He had taken no quinine for at least a week prior to this dose. On the following morning he looked slightly jaundiced and vomited bile-stained mucus. At noon he passed some very dark-red urine which was collected. At 3 30 he again passed dark-red urine and at 8 P.M. the urine had become normal in colour. Specimens of his blood were again taken. The urine was examined for me by Mr. Pakes who reported as follows. Specimen 1, collected at noon: Albumin, large amount; sugar, absent; and bile, present. The colour was due to the presence of hæmoglobin—not methæmoglobin—and the urine gave a very strong urobilin band. Under the microscope hyaline and granular casts were found as well as some renal epithelium. Spermatozoa were very numerous and there were a very few red blood discs. Specimen 2, collected at 3.30: This specimen was practically identical with No. 1. The red colour was certainly hæmoglobin. There were perhaps rather fewer casts and rather more red blood discs, but the difference was only slight. Specimen 3, collected at 8 0 P.M.: Albumin, faint trace; sugar, *nil*; and bile, *nil*. No hæmoglobin band could be found, but the urobilin band was still very marked. Microscopically neither red blood discs, casts, renal epithelium, nor spermatozoa could be found. On the following day the patient had a slight relapse of the hæmoglobinuria and he felt somewhat chilly. I therefore gave him more quinine and he rapidly improved. Three days later specimens of blood were taken, and also six days later. The specimens of blood taken whilst he actually had blackwater fever and those taken three and six days later were examined both by myself and by Mr. Pakes, but we failed entirely to find either amœboid or crescent parasites.

---

[2] An account of these may be seen in the Journal of Tropical Medicine 1899.

[3] Transactions of the Pathological Society, 1898 99.

[4] Transactions of the Epidemiological Society, 1898-99.

The precautions necessary for the prevention of blackwater fever may be therefore divided into two classes: (I.) Those necessary for the prevention of malaria; and (II.) those necessary for the prevention of blackwater fever in malarial subjects.

I.—THE PRECAUTIONS NECESSARY FOR THE PREVENTION OF MALARIA.

Since Ross's discovery that the mosquito is one of the causes of the spread of malaria it becomes necessary to take precautions against being bitten by mosquitoes. In malarious countries swampy land should be avoided as much as possible and houses should be built at a distance from the haunts of the mosquito. Mosquito-breeding pools and puddles should be filled up and drained or treated with kerosine or other oil, as has been suggested. In the part of Nigeria where I resided to do this efficiently would be an almost hopeless task, for, firstly, in the delta regions the rainfall is enormous, the land is only slightly raised above high-water mark, and it is frequently submerged; it is also intersected by a perfect network of creeks, streams, and puddles and is covered with a jungle so dense that native paths are only made and kept open with very great difficulty. In such a country even the most heroic measures would avail little. Secondly, as the land for hundreds of square miles is only slightly raised above high-water mark drainage obviously would be exceedingly difficult. Thirdly, any treatment of the mosquito-breeding pools with kerosene in regions like those forming the delta of the Niger would involve the expenditure of fabulous sums and Herculean labour. For these and other reasons very little can be done in the way of destroying mosquitoes by the above methods except in the immediate neighbourhood of European houses.

It seems to me that perhaps the only way in which we can hope to stamp out the mosquito is by introducing into the countries which it inhabits some animal which is inimical to it. A statement made to me by Lord Bennet appears to be worthy of mention here as possibly indicating the means which might be adopted. He says: "In the western States of America and in Canada there is a red parasite which destroys mosquitoes and almost exterminates them about the middle or end of July. The parasite is well known both in Ontario (away from towns) and in Washington State. I have found the parasite as early as the beginning of June." Doubtless there are many who are capable of giving us definite information as to the nature and habits of this parasite, if parasite it be. If therefore those who can will give us this information we shall be able to judge as to whether it would be possible or advisable to introduce this or some similar parasite into malarious regions. In addition to the well-known general precautions I should add that I consider the regular administration of quinine to be most important. My own custom has been to give five grains each day.

II.—THE PRECAUTIONS NECESSARY FOR THE PREVENTION OF BLACKWATER FEVER.

The prevention of blackwater fever in malarial subjects resolves itself practically into two points which I shall only briefly mention in this paper. 1. The general care of health. Chills, wettings, and exposure during the heat of the day should be avoided. Quinine should be regularly taken to eradicate the parasite and so prevent relapses and to cure fresh infections. Arsenic, iron, and other drugs which help to prevent or to cure anæmia should be taken. Patients should be moved from specially unhealthy localities. Special attention should be paid to proper housing and clothing and to the regular use of mosquito curtains. Any other illness—e.g., dysentery—should be cured as quickly as possible. Strict moderation should be observed in regard to alcohol, &c.; suitable food, which should include plenty of fresh vegetables, and a pure water-supply are of importance. Depressing drugs (such as antipyrin) should be taken with caution and should in no wise be taken in the place of quinine. As frequent visits as possible should be paid to non-malarious districts or countries. 2. Return to a non-malarious climate. When it is noticed that a man is becoming anæmic and debilitated by the fevers which he gets and by the conditions under which he lives, then he should be sent to a non-malarious climate for a protracted holiday. A place should be selected which is a suitable one for the patient to go to. Recently several cases of blackwater fever have occurred in men who have arrived in England in bitterly cold weather, and I think that some of these patients might have escaped had they been sent in the first instance to Grand Canary or Madeira.

THE SO-CALLED DANGER FROM THE USE OF BORIC ACID IN PRESERVED FOODS.

BY DR. OSCAR LIEBREICH.

IN a thorough investigation on the action of borax and boric acid I have not been able to demonstrate that these two bodies are included in the so-called toxic-acting substances in so far as they act through absorption from the intestine. My researches show that the misleading and frequently disseminated statements to the contrary are at present without foundation. This preliminary question must naturally be settled before the hygienic and legal aspects of the subject can be taken up—as to whether, and in what quantities, it is allowable to use these two substances as preservatives for articles of food. These questions are too often regarded, not from the purely scientific standpoint, but in the light of their value in the interest of political and agrarian parties in different countries. This is shown by the frequent republication of old and quite inconclusive investigations, particularly by the daily *press*, statements which are likely to mislead both legal and public opinion. It is not my intention to enter now into my investigations on this subject. These will appear in the *Vierteljahrsschrift fur Gerichtliche Medicin* and will shortly be published by Churchill in pamphlet form. The reason for my again taking up these questions is an article by Dr H. E. Annett on Boric Acid and Formalin as Milk Preservatives which appeared in THE LANCET of Nov. 11th, 1899 (p. 1282). It would be quite sufficient only to criticise this investigation, but it seems advisable also to make some introductory observations.

In the first place Dr. Annett cites the following from the report of the committee of the Local Government Board: "There is no doubt that boric acid if taken in large quantities would be injurious to health, but we have not sufficient information to show whether such such minute quantities as are generally added as preservatives would be regarded as having that effect, and more exact information is wanted before it can be decided whether a process which *prima facie* may be regarded as intended to prevent the loss of valuable foods must be held to be prohibited by law." Dr. Annett adds: "*It is remarkable that that 'sufficient information' on the action of minute doses of 'preservatives' habitually taken after the lapse of a period of almost 10 years is still not forthcoming.*" Dr. Annett is quite right. It is indeed strange that during 10 years of experimental work, taken part in by a great number of investigators it has not been forthcoming, and that during these 10 years of experience of practising physicians there has not been forthcoming any instance of injury to health from the administration of small doses of borax and boric acid. Particularly so, in my opinion, for during this time a very excellent opportunity has been afforded for practical observation, because the use of boric acid in small doses has been very extensively resorted to. This gives evidence to the experimenter that the existence of an injurious influence of small doses could only be demonstrated with great difficulty, if indeed it exists at all. One would expect that Dr. Annett had succeeded in obtaining the required proof. However, this is not the case. He begins by enumerating the injurious effects of excessively large doses in animals and confuses these with therapeutic observations. In such a scientific criticism it would have been fairer not to have suppressed the facts that excessive doses administered by the mouth cause only passing harm in man and that the injection of excessive doses of borax and boric acid in the body cavities of patients produces distinct intoxication and even death. This is well known and not to be wondered at; but from this latter fact no conclusion can be drawn as to their toxicity when administered through the stomach and intestine, for the purpose of forming a judgment on the use of small quantities for the

Grün." The sections do not show any very advanced change; there is, however, some necrosis of the epithelium of the convoluted tubules and Henle's tubes. The necrosis is superficial only, filling the lumen with granular débris. The nuclei of the necrotic cells do not stain well, they seem to be fewer in number, and are breaking up. There is no interstitial change and the glomeruli are unaffected. There are no hæmorrhages or deposition of pigment. The changes described are *consistent with an early parenchymatous* nephritis.

Liver.—Sections were cut in paraffin, stained with Ehrlich's hæmatoxylin and counterstained with "Licht Grün." The sections show very conspicuously the pigmentation of the hepatic cells. The pigment is distributed fairly evenly in all parts of the lobules. The granules of pigment vary somewhat in colour from pale yellow to brown or almost black. The pigment is contained in the general protoplasm of the hepatic cells, not in the nuclei. In the capillaries are to be seen endothelial cells also containing similar pigment and pigmented leucocytes. In addition to this pigmentation the capillaries between the hepatic cells are dilated throughout the section. The capsule of the organ is thickened. There is no increase of connective tissue in the substance of the liver.

Spleen.—Sections were cut in paraffin and stained with Ehrlich's hæmatoxylon. The sections show a widely spread and advanced degree of fibrosis. The capsule and trabeculæ are much thickened and fibrous and devoid of nuclei. The stroma of the pulp tissue is considerably increased. Scattered throughout the section are seen masses of pigment of varying size and colour, the colour being bright yellow or brown to almost black. The pigment is apparently in leucocytes and also lies free among the cells. The larger masses of pigment are found in the Malpighian bodies. The smaller vessels have a very marked thickening of their sheaths; the walls are degenerate and have very few nuclei; the lumen is much reduced or even obliterated.

Cerebrum.—Sections were cut in paraffin and stained with borax methylene blue. The sections show no definite changes; there is no deposition of pigment. The vessels appear to be normal. Owing to the long maceration in spirit which probably on account of climatic conditions on the Niger was not absolute, the capillaries of the cerebrum have no complete blood corpuscles in them, but only some granular débris. Under these circumstances it is, of course, impossible to demonstrate the malarial parasite which in these cases is said to be found in the capillaries of the brain. About a dozen sections in all were examined, but no satisfactory corpuscles were found.

It will be seen that so far as one can see the above sections show nothing that cannot be found in the tissues of a patient who has had several attacks of malaria. It would appear, however, that it is possible for a patient to have had malaria many times and yet show no pigmentation of any organ except the spleen. In two of the cases of blackwater fever published by Koch[2] he states that both patients had repeatedly suffered from fever which reacted to quinine; in one only the spleen showed pigment granules and in the other he states: "The deposit of pigment in the endothelium of the spleen and liver, so characteristic of malarial disease, was likewise lacking."

Before discussing the prevention of this disease it will be necessary to say—even at the expense of repetition—something concerning its cause. Last December Mr. W. O. C. Pakes and I[3] suggested that blackwater fever bore to malarial fever a similar relation to that borne by hyperpyrexia to rheumatic fever. I should like in the first place to examine Koch's cases. 1. It is strange that, although Koch inquires, "Therefore how can one still assert that blackwater fever is caused by malaria parasites?" *in all his cases which have so far been published*, in the *Journal of Tropical Medicine* there is a definite history of previous malarial attacks. 2. In all the cases except No. 7, where the patient had taken quinine, he took it because he felt unwell. In Case 7, although the patient felt well on the morning upon which he took the quinine, he had had intermittent fever for the preceding few days. 3. The cases of hæmoglobinuria published by Tomaselli which were caused by quinine did not, so far as I can make out, resemble blackwater fever in any other respect than in that of the presence of hæmoglobinuria. 4. If blackwater fever is, as Koch maintains it is, an intoxication by quinine no case of the disease could occur unless the patient had taken quinine. But I have already published a case[4] where the patient had no quinine until he had developed well-marked blackwater fever. 5. Koch concludes that "the lack of parasites in more than half of all cases, and the omission of the relapses would alone suffice to prove *that blackwater fever itself* cannot be malaria, but that it is pretty frequently associated with malaria." The lack of parasites during and subsequent to an attack of blackwater fever is of course well known, but I cannot see that any of these cases were examined for parasites *before* the attack of blackwater fever. The absence of relapses is to my mind very inconclusive since he makes no mention of the time during which they were under observation or of their surroundings during that time. It is not at all rare to find that a patient may be quite free from relapses of malaria for many months—in fact, there seems to be no doubt that some cases undergo a spontaneous cure. In short, I see no reason yet to modify the view which we suggested—that it is a complication of malaria. I quite agree to describe the condition as an intoxication, but of malarial origin.

The following case which I have recently had under my care is of great interest chiefly from the reason that I saw the patient before the attack of blackwater fever commenced.

A man, aged 22 years, had been to West Africa twice; during his first stay he had an attack of blackwater fever and he was quite recently invalided home for the same complaint. He arrived home in bitter weather and came to see me as he had felt unwell and chilly for two or three days, but during this time he did not lie up. I took several specimens of his blood and examined them. Some of the specimens were stained with carbol-thionin blue and others with eosin methylene blue. The hæmatozoa, which were fairly numerous were seen to be in two stages. All but two were about one-third of the diameter of the red disc in size, circular, oval, or in the shape of a signet ring and without pigment. The discs were not enlarged and the portions not occupied by the parasite took the eosin stain well. The two above mentioned were larger, occupying about two-thirds of the area of the disc (which, however, was not enlarged), with irregular edges and with several granules of pigment scattered throughout the hæmatozoon. On the same evening he went to a theatre, but feeling very ill went home, where upon his arrival he vomited. In consequence of finding parasites in his blood nine grains of the hydrobromate of quinine were taken by him after his return from the theatre. He had taken no quinine for at least a week prior to this dose. On the following morning he looked slightly jaundiced and vomited bile-stained mucus. At noon he passed some very dark-red urine which was collected. At 3 30 he again passed dark-red urine and at 8 P.M. the urine had become normal in colour. Specimens of his blood were again taken. The urine was examined for me by Mr. Pakes who reported as follows. Specimen 1, collected at noon: Albumin, large amount; sugar, absent; and bile, present. The colour was due to the presence of hæmoglobin—not methæmoglobin—and the urine gave a very strong urobilin band. Under the microscope hyaline and granular casts were found as well as some renal epithelium. Spermatozoa were very numerous and there were a very few red blood discs. Specimen 2, collected at 3.30: This specimen was practically identical with No. 1. The red colour was certainly hæmoglobin. There were perhaps rather fewer casts and rather more red blood discs, but the difference was only slight. Specimen 3, collected at 8 0 P.M.: Albumin, *faint trace; sugar, nil; and bile, nil.* No hæmoglobin band could be found, but the urobilin band was still very marked. Microscopically neither red blood discs, casts, renal epithelium, nor spermatozoa could be found. On the following day the patient had a slight relapse of the hæmoglobinuria and he felt somewhat chilly. I therefore gave him more quinine and he rapidly improved. Three days later specimens of blood were taken, and also six days later. The specimens of blood taken whilst he actually had blackwater fever and those taken three and six days later were examined both by myself and by Mr. Pakes, but we failed entirely to find either amœboid or crescent parasites.

---

[2] An account of these may be seen in the Journal of Tropical Medicine 1899).

[3] Transactions of the Pathological Society, 1898-99.

[4] Transactions of the Epidemiological Society, 1898-99.

The precautions necessary for the prevention of blackwater fever may be therefore divided into two classes: (I.) Those necessary for the prevention of malaria; and (II.) those necessary for the prevention of blackwater fever in malarial subjects.

I.—THE PRECAUTIONS NECESSARY FOR THE PREVENTION OF MALARIA.

Since Ross's discovery that the mosquito is one of the causes of the spread of malaria it becomes necessary to take precautions against being bitten by mosquitoes. In malarious countries swampy land should be avoided as much as possible and houses should be built at a distance from the haunts of the mosquito. Mosquito breeding pools and puddles should be filled up and drained or treated with kerosine or other oil, as has been suggested. In the part of Nigeria where I resided to do this efficiently would be an almost hopeless task, for, firstly, in the delta regions the rainfall is enormous, the land is only slightly raised above high-water mark, and it is frequently submerged; it is also intersected by a perfect network of creeks, streams, and puddles and is covered with a jungle so dense that native paths are only made and kept open with very great difficulty. In such a country even the most heroic measures would avail little. Secondly, as the land for hundreds of square miles is only slightly raised above high-water mark drainage obviously would be exceedingly difficult. Thirdly, any treatment of the mosquito-breeding pools with kerosene in regions like those forming the delta of the Niger would involve the expenditure of fabulous sums and Herculean labour. For these and other reasons very little can be done in the way of destroying mosquitoes by the above methods except in the immediate neighbourhood of European houses.

It seems to me that perhaps the only way in which we can hope to stamp out the mosquito is by introducing into the countries which it inhabits some animal which is inimical to it. A statement made to me by Lord Bennet appears to be worthy of mention here as possibly indicating the means which might be adopted. He says: "In the western States of America and in Canada there is a red parasite which destroys mosquitoes and almost exterminates them about the middle or end of July. The parasite is well known both in Ontario (away from towns) and in Washington State. I have found the parasite as early as the beginning of June." Doubtless there are many who are capable of giving us definite information as to the nature and habits of this parasite, if parasite it be. If therefore those who can will give us this information we shall be able to judge as to whether it would be possible or advisable to introduce this or some similar parasite into malarious regions. In addition to the well-known general precautions I should add that I consider the regular administration of quinine to be most important. My own custom has been to give five grains each day.

II.—THE PRECAUTIONS NECESSARY FOR THE PREVENTION OF BLACKWATER FEVER.

The prevention of blackwater fever in malarial subjects resolves itself practically into two points which I shall only briefly mention in this paper. 1. The general care of health. Chills, wettings, and exposure during the heat of the day should be avoided. Quinine should be regularly taken to eradicate the parasite and so prevent relapses and to cure fresh infections. Arsenic, iron, and other drugs which help to prevent or to cure anæmia should be taken. Patients should be moved from specially unhealthy localities. Special attention should be paid to proper housing and clothing and to the regular use of mosquito curtains. Any other illness—e.g., dysentery—should be cured as quickly as possible. Strict moderation should be observed in regard to alcohol, &c.; suitable food, which should include plenty of fresh vegetables, and a pure water-supply are of importance. Depressing drugs (such as antipyrin) should be taken with caution and should in no wise be taken in the place of quinine. As frequent visits as possible should be paid to non-malarious districts or countries. 2. Return to a non-malarious climate. When it is noticed that a man is becoming anæmic and debilitated by the fevers which he gets and by the conditions under which he lives, then he should be sent to a non-malarious climate for a protracted holiday. A place should be selected which is a suitable one for the patient to go to. Recently several cases of blackwater fever have occurred in men who have arrived in England in bitterly cold weather, and I think that some of these patients might have escaped had they been sent in the first instance to Grand Canary or Madeira.

THE SO-CALLED DANGER FROM THE USE OF BORIC ACID IN PRESERVED FOODS.

BY DR OSCAR LIEBREICH.

IN a thorough investigation on the action of borax and boric acid I have not been able to demonstrate that these two bodies are included in the so called toxic-acting substances in so far as they act through absorption from the intestine. My researches show that the misleading and frequently disseminated statements to the contrary are at present without foundation. This preliminary question must naturally be settled before the hygienic and legal aspects of the subject can be taken up—as to whether, and in what quantities, it is allowable to use these two substances as preservatives for articles of food. These questions are too often regarded, not from the purely scientific standpoint, but in the light of their value in the interest of political and agrarian parties in different countries. This is shown by the frequent republication of old and quite inconclusive investigations, particularly by the daily press, statements which are likely to mislead both legal and public opinion. It is not my intention to enter now into my investigations on this subject. These will appear in the *Vierteljahrsschrift für Gerichtliche Medicin* and will shortly be published by Churchill in pamphlet form. The reason for my again taking up these questions is an article by Dr H. E. Annett on Boric Acid and Formalin as Milk Preservatives which appeared in THE LANCET of Nov. 11th, 1899 (p. 1282). It would be quite sufficient only to criticise this investigation, but it seems advisable also to make some introductory observations.

In the first place Dr. Annett cites the following from the report of the committee of the Local Government Board:—"There is no doubt that boric acid if taken in large quantities would be injurious to health, but we have not sufficient information to show whether such such minute quantities as are generally added as preservatives would be regarded as having that effect, and more exact information is wanted before it can be decided whether a process which *primâ facie* may be regarded as intended to prevent the loss of valuable foods must be held to be prohibited by law." Dr. Annett adds: "It is remarkable that that 'sufficient information' on the action of minute doses of 'preservatives' habitually taken after the lapse of a period of almost 10 years is still not forthcoming." Dr. Annett is quite right. It is indeed strange that during 10 years of experimental work, taken part in by a great number of investigators it has not been forthcoming, and that during these 10 years of experience of practising physicians there has not been forthcoming any instance of injury to health from the administration of small doses of borax and boric acid. Particularly so, in my opinion, for during this time a very excellent opportunity has been afforded for practical observation, because the use of boric acid in small doses has been very extensively resorted to. This gives evidence to the experimenter that the existence of an injurious influence of small doses could only be demonstrated with great difficulty, if indeed it exists at all. One would expect that Dr. Annett had succeeded in obtaining the required proof. However, this is not the case. He begins by enumerating the injurious effects of excessively large doses in animals and confuses these with therapeutic observations. In such a scientific criticism it would have been fairer not to have suppressed the facts that excessive doses administered by the mouth cause only passing harm in man and that the injection of excessive doses of borax and boric acid in the body cavities of patients produces distinct intoxication and even death. This is well known and not to be wondered at, but from this latter fact no conclusion can be drawn as to their toxicity when administered through the stomach and intestine, for the purpose of forming a judgment on the use of small quantities for the preservation of food. We are aware that many substances are harmless in the intestinal canal if swallowed, but that if injected subcutaneously or into the body cavities they act as poisons. Further, Dr. Annett states that the most eminent authorities of this country, who by means of THE LANCET Special Sanitary Commission on the Use of Antiseptics in Food of 1896 published their opinions on the question of food preservatives, were unanimously of opinion that the use of antiseptics in food was injurious to health. Reference to the columns of THE LANCET convinces me that this statement is totally inaccurate It is only necessary to cite the words of two authorities. Professor Halliburton[1] says: "I and all of us are continually taking such food (especially milk treated with boric acid) without any appreciably bad results." And Professor Bradbury[2] says: "I am disposed to think that the presence of small quantities of salicylic, boric, or benzoic acids, in sufficient quantities to preserve it is not injurious to health." The conclusion of THE LANCET itself was as follows: "As will be seen from these communications there is considerable diversity of opinion as to whether antiseptics in the quantities used for preserving food are injurious to health, and also whether legislation could satisfactorily deal with the subject, although on the whole the conclusion appears to be not altogether unfavourable to the use of preservatives with certain restrictions. The majority agree in one thing, and that is that should the practice be tolerated it should be placed under some control, so that, for instance, where the addition of antiseptics is practised it should be notified to the purchaser. Very few of our correspondents, it is important to note, are able to quote cases within their experience of injury to health having been caused by preservatives in food."

One can be certain that if medical men of the standing of Dr Lauder Brunton and others had been able to satisfy themselves that the small quantities of antiseptics necessary possessed even a trace of injurious influence they would at once have concluded it was altogether better to entirely forbid the preservation of food. From the researches of this commission it can also be inferred that the authorities referred to held that it was better to preserve food with these small and non-injurious quantities of antiseptics than that any section of the public should be obliged to eat decomposing food, regarding the injurious nature of which no doubt exists. Dr. Annett quotes Binswanger also incorrectly. More extensive quotation would have clearly shown that as the result of his investigations Binswanger held that small doses of boric acid exercised not only no injurious action but so little action whatever that it was practically inert. These misquotations have already been corrected in my pamphlet, but it seems to me necessary to refer to one more important point.

Dr. Annett himself draws attention to the fact that the only direct instance of the injurious action on man of boric acid when added to milk is that recorded by Dr. A. R. Robinson[3] and referred to by Dr. Annett in the following words: "Five of the seven inmates of a certain house became suddenly ill after partaking of blancmange which had been made from milk of the previous day, to which, as was confessed, the dairyman supplying it had already added boric acid and to which the cook had added a further quantity to preserve it over-night. Nine fowls fed liberally with the blancmange became ill, five dying." From such a description it is not possible to form any idea as to what the nature of the illness of the inmates was One may pass over the question as to what symptoms were exhibited by the hens, and what were the appearances that would have been present in the post-mortem examination (which was not made), and I put to Dr. Robinson the question if he has not observed, after blancmange, after ice, and particularly after milk, similar sudden illness without any boric acid having been present. It is not uncommon for illness to ensue if food has been kept in vessels in contact with metal, as in the case of blancmange often occurs. But the first question for a sanitary officer to settle was the mode of preparation of the blancmange. In the cookery books of different nations the ingredients are stated as follows: Milk or cream, bitter almonds, sugar, gelatin, vanilla, lemon peel, and bay laurel leaves. From this it is evident that it is not impossible that things may have been present which are known to afford opportunities for poisoning to occur. Vanilla is often such a cause, and the possibility for poisoning even by prussic acid exists through an excess of bitter almonds being used. The bitter taste of these is by no means a protection to the people partaking of the food, for the laurel leaves and lemon cannot only conceal this, but the combination with bitterness may also add an extra flavour. Also the milk may have already been poisonous before the addition of the boric acid, and it is well known that boric acid only prevents the further formation of toxic bodies without destroying those already existing. Of not one of these possible contingencies has Dr. Annett taken any account and it is now impossible to determine whether any of these same factors were present. One can, however, through investigations on hens, prove Dr. Robinson's assertion that the boric acid contained in the blancmange was the cause of the illness of the people and of the hens is without foundation. It should have been Dr. Robinson's work to investigate this and show whether hens can be poisoned or not by feeding them on blancmange to which boric acid has been added before he alarmed the world by making public so startling an assertion. For this purpose it was only necessary to clear up the whole question by so simple an experiment as the following.

I placed nine fowls for several days on ordinary *corn*-feeding, and observing that one showed some signs of respiratory trouble it was discarded and the following investigation was carried out on the remaining eight. On the first day one litre of milk and six grammes and five decigrammes of boric acid and 200 grammes of maize-flour were made into a thick porridge, which was equivalent to one ounce and 16½ grains in one gallon. This corresponded to a blancmange, and on it the hens were fed. On the second day they received the same feeding, and on the third day half of the same feeding. In three days the hens had each received about two grammes, or 30 86 grains, without any disturbance in health being noticeable. Their eagerness to eat corn was in no way diminished. On the twelfth day seven of the hens at 1 P M. received 10 pills, each containing 0 05 gramme of boric acid—i e., each received 0·5 gramme, or 7·72 grains. At 3 P M. the same dose was repeated, so that every animal had received one gramme, or 15 43 grains. The eighth hen received 50 grammes of sweet almonds. On the thirteenth day no appearance of illness had manifested itself, and on the sixteenth day the fowls appeared perfectly well.

From this it is fully proved: (1) that if blancmange be prepared with milk and boric acid added even in such excessively large quantity as 6 5 grammes in a litre (or one ounce and 18½ grains in a gallon) it is not poisonous, and further that boric acid itself in such large doses as one to two grammes (or 15 43 to 30 86 grains) exercises no toxic effect on hens; (2) that the toxic appearances observed by Dr. Robinson in the hens did not arise from boric acid; and (3) that Dr. Robinson has not succeeded in ascertaining the true cause of the sickness which affected the hens and the inmates of the house It is not necessary to state that my experiment on the hens has no other value than to prove Dr. Robinson's error.

Another point in Dr. Annett's article concerning the feeding of kittens requires to be gone into Such experiments are extremely serviceable to the inquiry, but in the present instance the experiments performed do not fulfil their intended purpose, viz., to prove the toxic effect of *small* doses of boric acid when given for a long time. All that these experiments prove is already known, viz., that animals finally succumb under the repetition of large doses. I regret the necessity for adversely criticising these experiments, nevertheless, it is not stated how much the kittens ate, and the experiments show that conclusions based on only two series of experiments are founded on insufficient data, since two of the kittens fed on milk containing 40 grains died earlier than any of those fed on milk which contained 80 grains. It is necessary in order to form a reliable judgment concerning the feeding of kittens to have a long series of experiments. As I have stated, the difficulty is here present that the data given are imperfect. They permit, however, of a conclusion being drawn. One comes to the following results. If we take a solution of 40 grains in the gallon, corresponding to the second series of experiments, then there are 2 592 grammes in 4·545 litres (i.e., in one gallon) or 0 57 gramme in one litre. However, in the data given by the experimenter it is not stated how much of the milk the kittens consumed It may have been a small quantity, say 100 cubic centimetres, which each kitten drank In this case the animal ingested 0 057 gramme or 0 88 of a grain of boric acid The mean weight of the kittens in the series was 408 4 grammes

---

[1] THE LANCET, Jan 2nd, 1897, p 59.

[2] Ibid

[3] Public Health, August, 1899

It must now be settled to what age in a child these three weeks old to four weeks old kittens are comparable If we accept that a man grows till he is 20 years of age and that a cat grows till it is two years old, then the kittens experimented on may be compared to children of from nine to 10 months old A child of this age has a weight of, it may be eight kilogrammes and 300 grammes, and corresponding to the weight of the kittens such a child would require to receive 1·13 grammes or 17 44 grains of boric acid To obtain this it would be necessary for a child to use one litre and 983 cubic centimetres of the milk consumed by the kittens (0 57 gramme of boric acid in one litre) But such a child at the very utmost could only partake of one and a half litres per day, which would contain 0 86 gramme, or 13 25 grains, of boric acid To make a general comparison with the experiments on the kittens since the child has a weight of eight kilogrammes and 300 grammes and the kittens of 408 4 grammes, the kitten ought to have received no more than 0 042 gramme of boric acid, and this quantity must be contained in 100 cubic centimetres This would correspond with milk containing only 0 42 gramme per litre or 29 45 grains per gallon, while as much as 40 grains per gallon was used in these kittens This difference of more than 25 per cent of the stated quantity of boric acid is very important, particularly when the treatment is continued over a long period According to this calculation, made in a very favourable light from the experimenter's standpoint, it is evident that Dr Annett is very far removed from having proved by his experiments that small quantities, if used for a long time, are poisonous for men and children

THREE CASES IN WHICH MOVEABLE KIDNEY PRODUCED ALL THE SYMPTOMS OF GALL STONES

BY T J MACLAGAN, M D EDIN, M R C P LOND,

AND

FREDERICK TREVES, F R C S ENG

CASE 1 —A woman, aged 35 years, a widow with no children, tall and of spare habit, consulted me [Dr Maclagan] in 1892. She had never had any serious illness, but for the last three years had suffered from occasional attacks of pain in the epigastrium, from indigestion and general loss of strength She was thin and not well nourished, her complexion was sallow, she was somewhat anæmic and had the expression of one who suffered a good deal She said that she was never quite well, had always more or less discomfort in the abdomen, and every now and then had an attack of severe pain—so severe as to make her call out These attacks lasted sometimes for an hour or two, sometimes for eight or 10 hours, and sometimes for a whole day. The pain was referred to the hepatic and epigastric regions The attacks had of late become more frequent as well as more severe; she seldom went a week without one and was getting worn out by them After the attacks she was generally slightly jaundiced for a few days She had consulted various physicians, some of whom regarded the pain as neuralgic and others thought that she had gall stones She underwent a course of treatment at Schwalbach without deriving any benefit from it She did the same at Carlsbad the following year From this she said she derived some benefit, but the excellent physician who looked after her there told her that she had a large gall stone in her gall bladder and that she would be no better till it was removed When I saw her first she had considerable discomfort but was not in pain There was tenderness on pressure over the epigastrium and at the edge of the left lobe of the liver; the gall bladder could not be felt The right kidney was very moveable and could be distinctly felt under the edge of the liver No other abnormality was found A week later I saw her in one of her attacks of pain She was suffering much, the pain being referred to the epigastrium and to the right of it. The pulse was quick and feeble and the temperature was 99 8°F, She was tender to the touch over the seat of pain and the gall bladder could be felt full and distended The least pressure over it caused considerable pain She had a dose of morphia and the pain passed off, leaving her slightly jaundiced for a few days It was some days before the abnormal tenderness on pressure disappeared A fortnight later she had another attack in all respects similar, and within the following three months she had five or six more During each attack the gall bladder filled up and after each she was slightly jaundiced for two or three days The kidney could always be detected under the border of the liver The character of the attacks and the symptoms produced all pointed to the presence of a gall stone in the gall bladder small enough to get into the cystic duct but too large to pass through it This was explained to the patient and an operation was recommended for the removal of the stone and fixing of the kidney Mr. Knowsley Thornton saw her with me and concurred in this view On May 5th, 1893, he performed the operation He first, by an incision in front, got at the gall bladder Nothing was found amiss with it The gall bladder and gall ducts were carefully examined but no gall stone was found, but behind it was felt a lump which turned out to be the right kidney The wound in front was closed by stitches The kidney was then reached by incision in the lumbar region and secured to the side by three silk sutures The wounds healed rapidly, the patient made a good recovery, and six weeks after the operation went to the country to recruit She remained well and has had no recurrence of her old symptoms

CASE 2 —The patient was a woman, aged 34 years, the mother of three children She had a history of having suffered from gall stones for five or six years On Nov 17th, 1892 I saw her with Dr J Smith of Windsor For two days she had been suffering from severe pain in the epigastric and hepatic regions pain which was kept down only by injections of morphia She was quite jaundiced, the temperature was 101° F, and the tongue was dirty The gall bladder could be felt full and distended, it was very tender, but as she was a good deal under the influence of morphia there was not much difficulty in examining it On the following day the pain abated and she was able to do without the morphia A gall stone was found by the nurse in the stool She remained jaundiced for a week or 10 days She consulted me again in 1893 She said that she had never really been well since I saw her in 1892 She was constantly having attacks of pain seldom going more than a week without one For the relief of these she took opium She was sallow thin and had a look of ill health There was tenderness on pressure over the epigastrium and the region of the gall bladder but no swelling or fulness The right kidney was very moveable and could be felt under the edge of the liver I dieted her, gave a mixture containing sulphate and bicarbonate of soda and enjoined a quiet life In 1895 she again consulted me for the same symptoms and received the same treatment I did not see her again till the spring of 1897 when she came to London to be under my care She told me that she was steadily getting worse, the attacks being more frequent and more severe, so much so that she seldom passed more than two or three days without having to take morphia for the relief of the pain She was thin, badly nourished, and slightly jaundiced There was tenderness on pressure over the epigastrium and over the region of the gall bladder, but no distinct fulness The right kidney could be felt as before under the liver and was very moveable Though no gall stone was found in the stools there seemed no doubt that every few days a stone was either passing or trying to pass She was getting worn out by the pain and though in time the gall bladder might empty itself this seemed too great a risk to run I explained the circumstances to the patient and to her husband and recommended an operation for the removal of the stones Mr. Treves saw her with me and quite concurred both in my view of the case and in the advisability of operating The patient was suffering so much and her life was such a burden to her that she readily assented On May [illegible] 1897 the operation was performed Mr Treves had better tell this part of the story —" Immediately the abdomen was opened the gall bladder presented It was very much enlarged and was fully distended It was readily emptied by pressure and was found to be free from gall-stones as were also the biliary ducts. There were no adhesions. On examining the neck of the gall-bladder the kidney was encountered. Its upper end was actually lying on the cystic duct and the gland had to be displaced before the ducts could be examined. There was no evidence that the disturbance of the peritoneum attending the moveable kidney had led to such a mobility of the duodenum as could produce a kinking of the duct. The condition discovered definitely suggested that the kidney pressed directly upon the biliary passages. The gall-bladder was not opened and the abdominal wound was closed. An incision was then made in the loin and the kidney—which was very moveable—was secured by three silk sutures. The fact remains that the patient was cured of attacks of hepatic colic attended by jaundice by the fixing of her right kidney." The patient made an excellent recovery and went to the country six weeks after the operation. She has had no return of pain and now, two and a half years after the operation, remains well. She has gained in flesh and looks the picture of health. I accidentally met her two years after the operation and did not recognise her at first so much had her appearance changed for the better.

CASE 3.—A woman, aged 34 years, the mother of two children, of spare habit, had suffered for three or four years from indigestion, pain in the epigastrium, and symptoms of biliary catarrh. At times she had attacks of pain in the epigastrium and the region of the liver. During these attacks the gall-bladder could generally be felt more or less distended, and after each she was slightly jaundiced. The right kidney was moveable and could be felt under the liver. She improved at times under treatment, but never got well. During the winter 1897-98 matters got worse. Attacks of pain were more frequent as well as more severe. She lost flesh and was persistently slightly jaundiced. In the interval between the attacks there was more or less tenderness on pressure over the epigastrium; during them this tenderness was more marked, and, in addition, the gall-bladder could be felt full and distended, and was very tender. There was usually a slight rise of temperature. The diagnosis formed was that the gall-bladder contained a gall-stone which was small enough to enter the cystic duct but too large to pass through it. I had the advantage of having the opinion of Sir William Broadbent and of Mr. Treves, who both took the same view. It was decided to go on treating her medically in the hope that the stone would yet pass. She seemed to improve a little. In July, 1898, she went to Harrogate for a course of waters which seemed to do her much good. From there she went to America, where she spent the winter of 1898-99. There she got much worse, was constantly laid up with attacks of pain the same as before, only more severe. There the physician who attended her, Dr. Kinnicut of New York, treated her for gall-stones. She returned to London in April, thin, slightly jaundiced, and much worn by suffering. She was scarcely ever free from pain and every few days had a severe attack calling for the use of morphia. The gall-bladder could now always be felt; during an attack it was very tender and could be felt, to use Mr. Treves's simile, "like a small banana" in the abdomen. The right kidney was still displaced and very moveable. After watching her for a few weeks I felt that I was not justified in temporising any longer. The gall-bladder was so permanently distended and so tender that the patient ran the risk of acute inflammation and suppuration there. Again Sir William Broadbent and Mr. Treves saw her with me. They quite agreed that there was distinct risk in allowing matters to go on and that the gall-bladder should be opened and the stone removed. The patient and friends readily consented and the operation was performed by Mr Treves on June 30th, 1899. Again, as in the last case, no stone was found. What was found Mr. Treves shall describe. "An incision was made in the upper part of the right semilunar line. The gall-bladder presented and was not less than four times its normal size. It was opened by an incision made in the fundus. A considerable part of the body of the gall-bladder was adherent to the great omentum. The bladder was emptied and I introduced my forefinger. On reaching the neck of the gall-bladder I encountered a tumour which pressed upon that part and which was very readily felt through the anterior wall of the viscus. An examination with the disengaged hand showed that the 'tumour' was the upper end of the right kidney. There is no doubt whatever but that the kidney was directly pressing upon the cystic duct. No gall stones were found. The opening in the gall-bladder was closed by a double line of sutures and the abdominal wound was also closed. A second incision was made in the loin, and the right kidney, which was very moveable, was secured by three silk sutures. In this, as in the previous case, attacks of hepatic colic, attended by some jaundice, were cured by suturing the right kidney." The patient went on well without any drawback for 12 days, when she was suddenly seized with great oppression of breathing, urgent cough, and bloody expectoration due to pulmonary embolism. She gradually recovered from this. The cough which persisted for some time was most unfortunate for the abdominal wounds, but notwithstanding it all went well and she left London for the country on August 8th, rather less than six weeks after the operation. Now, four months after it, she has a look of health, has a good colour, has gained considerably in flesh, and has had no return of her old pain. The only thing complained of is some pain and discomfort in the right side and extending down towards the groin. This no doubt is due to the stitches in the kidney and the drag on them.

The point of these three cases—the point which is specially desired to bring before the profession—is that all the symptoms of gall-stones—attacks of hepatic colic followed by jaundice—may be produced by pressure on the bile ducts by a displaced right kidney. In each of these three cases the symptoms were exactly those produced by gall-stones; and that the symptoms were due to that cause was the diagnosis formed by all the physicians and surgeons who saw them. *In not one of them was a gall-stone found.* In each the symptoms were due to the same cause, the pressure on the bile ducts of a displaced kidney, a pressure which was, from the nature of the disturbing cause, not continuous but occasional and intermitting—so mimicking exactly what occurs in gall-stones. In Cases 1 and 3 the pressure was on the cystic duct and the jaundice therefore was less marked and the pain probably less severe; in Case 2 the pressure was on the common duct and the jaundice more marked in consequence. It is to be noted, too, that this patient was said once to have passed a gall-stone which was found in the stool.

Literature.—Murchison thus enumerates the causes which may produce jaundice by pressure on the bile duct from without: (1) tumours projecting from the liver itself; (2) enlarged glands in the fissure of the liver; (3) tumour of the stomach; (4) tumour of the pancreas; (5) tumour of the kidney; (6) post-peritoneal or omental tumour; (7) an abdominal aneurysm; (8) accumulation of fæces in the bowels; (9) a pregnant uterus; and (10) ovarian and uterine tumours (Diseases of the Liver, p. 336). There is no mention of moveable kidney. But this must be added to Murchison's list. The recognition of this agency as an occasional factor in causing jaundice is recent, and by no means generally accepted. But that it has to be accepted and dealt with as a clinical fact is demonstrated by the cases now recorded.

There is little literature on the subject, first because it is only of recent years that displacement of the kidney has had its clinical importance recognised, and secondly, because it is the still more recent advance in abdominal surgery that has demonstrated how serious a cause of disturbance such displacement may be. Dr. Hale White has recorded a case of jaundice caused by the pressure of a moveable right kidney on the bile ducts in which the jaundiced condition was cured by fixing the displaced kidney.[1] Dr. Cordier of Kansas has recorded a case of moveable kidney in which the gall-bladder was found to be distended and in which the patient was at times slightly jaundiced. "The enlargement of the gall-bladder could be made to disappear in a measure showing that there was not a permanent or complete obstruction of its duct. That no further mistakes be made in her case I made a small anterior opening over the gall-bladder and explored it and its duct for stones, but none were found. This incision was closed and the usual lumbar incision was made, and the moveable kidney was anchored with three silk sutures to the fascia and muscles. Since the operation all her gall bladder symptoms have disappeared, and her appetite, digestion, and assimilation have greatly improved, and she writes me that she feels better than she has done for years."[2]

The peculiarity of the three cases now recorded is that all the symptoms of gall-stones—recurrent attacks of hepatic colic followed by jaundice—were produced by the displaced kidney. But for the operation undertaken for the relief of these symptoms the true cause of the disturbance would not have been recognised. Before the days of modern abdominal surgery these patients would have gone on indefinitely, leading lives of suffering and misery, with the constant risk of more serious trouble arising. The demonstration of the true cause of the disturbance is due to modern surgical advance. The point to be accentuated is that hepatic colic and jaundice may be produced by the pressure on the bile-ducts of a displaced kidney.

A CASE OF HÆMORRHAGIC ASCITES.

BY THEODORE FISHER, M.D., M.R.C.P. LOND.,
PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY AND PHYSICIAN TO OUT PATIENTS TO THE BRISTOL HOSPITAL FOR SICK CHILDREN.

THE case of hæmorrhagic ascites published by Dr. G. S. Middleton in THE LANCET of Nov. 11th, 1899, p. 1286, recalled to my mind the following case, a brief note of which may be interesting.

A woman, aged 38 years, a domestic servant, was admitted into the Bristol Royal Infirmary on Jan. 20th, 1898, under the care of Dr. A. B. Prowse, to whom I am indebted for kind permission to publish the case. Four weeks before admission after being out-of-doors one evening she had felt cold and could not keep warm even in bed. She had been more or less "chilly" from that time. Two or three days after the onset of the cold sensation some swelling of the abdomen was noticed. Pain in this region quickly supervened and there was occasional vomiting. The bowels were constipated. The motions at first were of black colour but later became yellow. The urine from the onset was high-coloured and turbid. On admission to the Bristol Royal Infirmary the patient's abdomen was very distended and measured 37 inches in circumference. General tenderness was present and the greater part of the abdomen was resonant, but shifting dulness was present in the flanks. There was nothing noteworthy in the physical signs of the heart and lungs. The urine was high coloured and there was abundant deposit of mucus and urates. Neither albumin nor sugar was present. The temperature was subnormal (97° F.). The abdominal pain continued. On the 22nd the bowels were moved four times and the motions contained much blood and mucus. The patient died suddenly on the 24th during a severe attack of abdominal pain.

At the necropsy the patient was found to be a stout woman with very distended abdomen and some œdema of the legs. The peritoneal cavity contained about 12 pints of deeply blood-stained fluid. The small intestine from the duodenum downwards was intensely congested and of a deep purplish colour. The congestion of the ascending colon was less marked and the transverse colon, descending colon, sigmoid flexure, and rectum were quite unaffected. There were numerous petechiæ dotted over the peritoneal coat of the congested intestines and in places thin flakes of exudation were present. The veins of the mesentery were greatly distended and full of blood-clot, none of which, however, appeared to be ante mortem. The veins running over the surface of the stomach were similarly distended and full of blood clot. The portal vein also was about double its normal size and was full of blood-clot of blackish-purple colour, like that present in the other veins. The divisions of the portal vein throughout the liver were also greatly distended. The hepatic veins were abnormally full but contained no ante mortem thrombi. There was nothing abnormal in the inferior vena cava. The mucous membrane of the stomach was free from congestion. The duodenum was injected, but the colour of its mucous membrane was pale compared with that of the jejunum and ileum. The congestion of these divisions of the small intestine was intense and a large quantity of blood was mixed with the fæces in their interior. The mucous membrane of the ascending colon was also congested but to a much slighter extent. The wide area of congestion in the small intestine was free from the sticky mucus seen covering patches of congestion present in acute enteritis. The mesenteric veins and arteries were opened but no ante-mortem thrombosis was present. Beyond the distension of the veins above mentioned the liver showed nothing noteworthy. It weighed 48 ounces. The spleen was enlarged, weighed 16 ounces, but was not softer than normal. There was nothing abnormal in the suprarenal bodies, pancreas, or kidneys. Both pleural cavities contained ten ounces of clear fluid. The trachea, bronchi, and lungs showed nothing noteworthy, but there was a very large congested lymphatic gland, of the size of a small hen's egg, situated below the bifurcation of the trachea. The heart and pericardium were free from disease. Cultures were taken by Dr. J. O. Symes from the spleen and from the enlarged lymphatic gland, but only the bacillus coli communis was found.

The congestion of the intestines followed closely the distribution of the superior mesenteric vein and I expected to find thrombosis of that vein. I was, however, disappointed; the superior mesenteric vein contained merely soft, dark post-mortem clot and the portal vein showed distension fully equalling in degree that of the superior mesenteric vein. Yet to the naked eye the divisions of the portal vein in the liver were free from ante-mortem thrombus, as were also the hepatic veins, which I have seen thrombosed alone, leading to great congestion of the liver. Neither bacilli nor other micro-organisms were seen in microscopic sections of the liver stained by Gram's method and with methylene blue and fuchsin, but the small divisions of the portal vein showed organising thrombi in their interior. Only one small piece of the liver was taken for histological purposes and the discovery of thrombi in one small area does not prove that they were present throughout the substance of the liver. But while such absolute proof is wanting it must be allowed that extensive thrombosis of the small divisions of the portal vein would in great measure explain the congestion of the small intestine and the ascites. Such thrombi, however, whether limited in extent or widespread, must have been merely one of the morbid evidences of more abstruse pathological factors. The failure to discover some definite micro-organism does not prove that it was not present. The history given by the patient of a "chilly" feeling at the onset suggests a rise of temperature, and a rise of temperature further suggests some acute or subacute infection, and it is reasonable to suppose that such infection, if present, took place by the alimentary canal through some article of food.

Clifton, Bristol.

A CASE OF MULTILOCULAR CYSTIC EPITHELIAL TUMOUR OF THE JAW; EXCISION OF HALF THE LOWER JAW; RECOVERY.

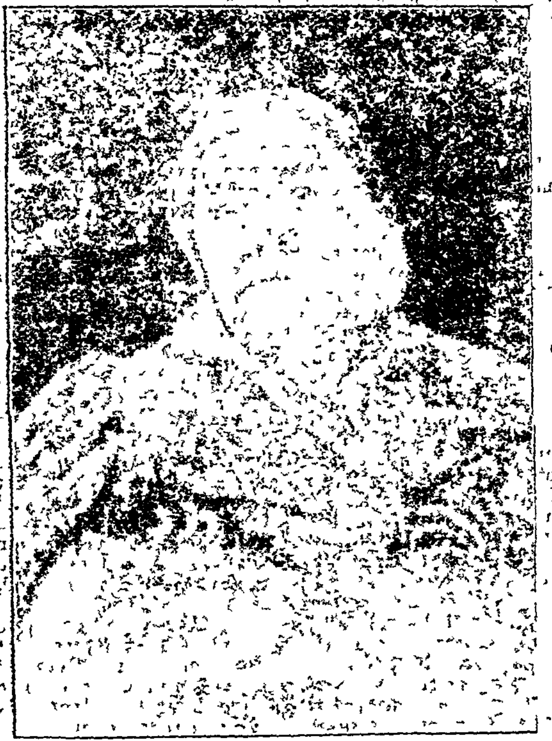
BY G. P. NEWBOLT, M.B. DURH., F.R.C.S. ENG.,
HONORARY SURGEON, LIVERPOOL ROYAL SOUTHERN HOSPITAL.

CASES of multilocular cystic epithelial disease of the jaw in which the tumour has attained a large size before removal are not very common. This case, therefore, may prove of interest to the profession.

A woman, aged 66 years, a widow, consulted me in August, 1897, regarding a tumour of the lower jaw of a cystic nature which she said had been growing for 20 years. A few days later, the patient being placed under chloroform, I laid open the cysts and gouged the parts freely, hoping that an operation of this kind might give her relief for some time. About January, 1899, however, there was a decided increase in the size of the tumour, and on May 15th she came into the Liverpool Royal Southern Hospital for removal of the growth (Fig. 1). On the 16th I removed the left half of the lower jaw with the tumour involving it. It was necessary to split the lip through, but I had very little difficulty in disarticulating the bone and the coronoid process came out with the growth intact, none of the cysts being opened. Hæmorrhage was profuse, but there was no difficulty in checking it. The wound was closed, a drain being left at the posterior angle. The patient made an excellent recovery and was able to be up and about the ward at the end of 10 days and the wound healed soundly in three weeks (Fig. 2).

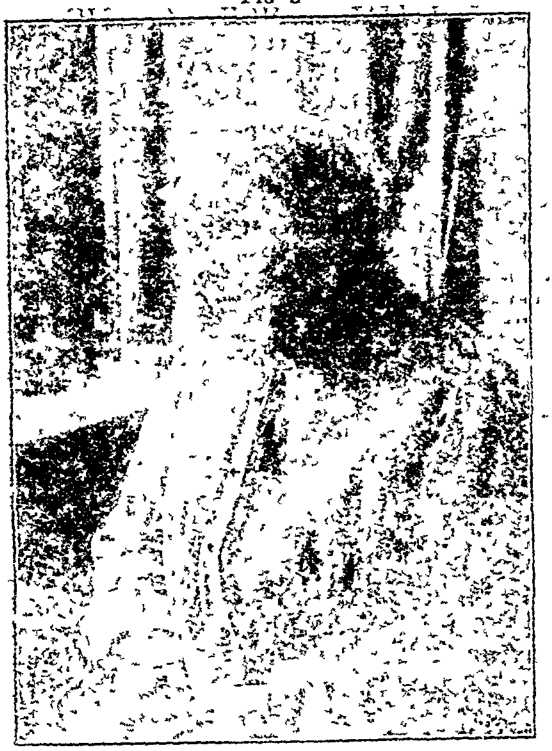
An examination of the parts removed showed that the tumour consisted of the left half of the lower jaw distended by cysts, which varied in size from a pin's head up to a large orange. One large cyst, projecting outwards formed the bulk of the tumour Its walls were made up partly of bony plates and partly of fibrous tissue, the interior being lined by a smooth, shiny membrane somewhat resembling the mucous membrane of the mouth. This large cyst communicated with other cysts, and across its cavity stretched fibrous bands, evidently the remains of a partition between it and some other cyst. The contents of the larger cysts resembled chocolate in colour and consistency, but in the smaller ones the fluid was clear and mucoid. The coronoid process of the jaw was hollowed out right up to its tip and the condyle was involved as far as the neck, so that it stood out like a button from the growth. The cut surface near the symphysis clearly showed that the growth originated in the central or cancellous portion of the jaw, distending the outer compact wall, and here was also some solid material which had not yet become cystic. The three teeth in the part removed were in the roof of a large cyst. On making sections of a small cyst which had thrown out a process I found that the cyst consisted of a wall of fibrous lamellæ lined on the inside by columnar epithelium. In the process of the cyst was more solid matter, and here I found masses of epithelial cells breaking down in the centre and forming cysts In cysts of the size of a hazel nut I found traces of epithelial lining, but in the largest cysts this had disappeared altogether. On the outside of the jaw near the teeth there was a solid portion of tissue which was made up of epithelium becoming cystic. An examination of the gum over the tumour showed that it was fairly normal, but at one point the epithelium showed signs of growing in. The tumour was therefore a multilocular cystic epithelial tumour.

FIG. 1.



Before operation.

FIG 2



After operation

After the gouging operation which I did on this case in 1897 I could find no traces of epithelium in the parts removed; but I had not at that time any of the solid portion of the tumour from the margin of the growth and I therefore drew erroneous conclusions concerning its nature It was not until the growth had broken through the bony wall of the jaw that the increase in size took place. The tumour then became painful from pressure on surrounding parts setting up severe neuralgia; there was also some pressure on the pharynx and difficulty in taking food. As the tumour had lasted 20 years some idea of the slowness of its growth may be gained. I could get no history of tooth irritation at the commencement of the disease. The microscopical sections show every stage from the mass of epithelial cells to the fully developed cyst.

Liverpool.

AN UNUSUAL CASE OF EMBOLISM IN THE FUNDUS OCULI.

BY H WRIGHT THOMSON, M B, C.M. GLASG.,
ASSISTANT OPHTHALMIC SURGEON, GLASGOW ROYAL INFIRMARY.

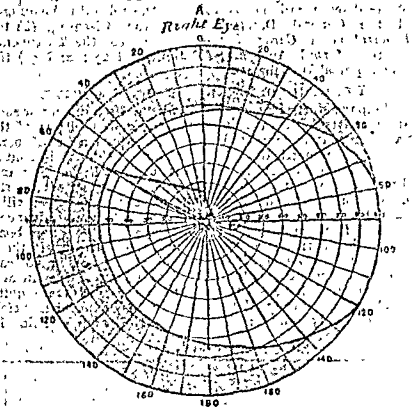
EMBOLISM of the central artery of the retina, is a lesion which, though not very common, is well known and very definite in its symptomatology and sequelæ. Embolism of a branch of the retinal circulation is, however, a very uncommon affection, as borne out by reference to text-books on ophthalmology. Thus Berry mentions having seen one case of embolism of a branch of the central retinal artery, and although he does not state which branch it was the progress of the case would indicate that it was not the macular artery which was affected, and Schobl[1] refers to several cases of macular embolism reported by Perls as occurring in the clinic of Hirschberg.

A young woman, aged 19 years, first consulted me at the eye dispensary of the Glasgow Royal Infirmary on May 11th, 1899, but in view of the advantages likely to attend indoor treatment I referred her to the ophthalmic department of the infirmary, where she was admitted under the care of Dr. A. Maitland Ramsay, to whom my thanks are due for permission to follow out and publish the case. The history was that three days previously the patient had been sitting at the window of a room and after rising and going to a dim corner she noticed on looking towards the fire that the sight of the right eye had become very much obscured. Her movements had not been sudden nor had she exerted herself in any way apart from rising and walking. There was no pain and the dimness of vision reached its maximum intensity instantaneously. She stated that for three years she had been troubled with attacks of transitory blindness of the right eye, occurring sometimes as often as two or three times a month They were but momentary in duration and recovery was always sudden and complete. They bore no obvious relationship to menstruation. As a worker at a tobacco factory her eyes were not subjected to any great strain and they were noted to be almost emmetropic. At the age of nine years she had suffered from chorea, and on examination of the chest there was found a rough ventricular systolic aortic murmur well propagated into the carotids which were visibly pulsatile. The urine cast an abundant sediment of urates. There was a trace of albumin present and microscopically a few epithelial casts were seen. Vision, as tested in the ordinary way, seemed reduced to perception of light, but on holding up a finger at a distance of one foot and directing the patient to look at the point she stated that she could not see the top part of it at all, but that the lower half was plainly visible. Examination with the perimeter revealed an area of absolute blindness, as shown in the chart. Owing to the limited area of the scotoma light perception in it was difficult to test accurately, but it certainly was much diminished, if not absolutely abolished. On ophthalmoscopic examination the optic disc was found to be œdematous, with its margin, except at the upper part, very indistinct. On the outer side the disc seemed to merge into a pale, almost white, slightly œdematous area, of shape and extent as shown in Fig. 2.

---

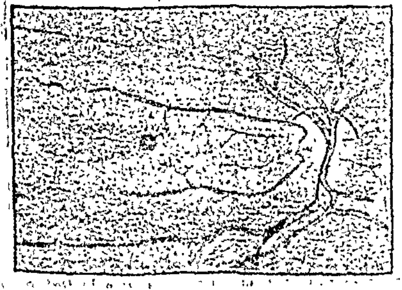
[1] Norris and Oliver's System of Ophthalmology.

FIG. 1.



The shaded area extending out from the centre of the chart represents the area of blindness in the field of vision.

FIG. 2.



Appearance of fundus when first seen. The area of lighter shading shows the extent of the ischæmia.

There was a circular, cherry-red spot in the macula. Its diameter was about one-fifth that of the disc and its deep red colour contrasted strongly with that of the normal fundus which extended right up to its temporal border. The macular artery emerging from the optic disc at a spot near its lower and outer margin was seen to divide at once into two branches, which, in comparison with those of the other eye, were small in size and embedded, especially the upper, in œdematous exudation. The retinal veins as a whole were distinctly engorged, while the arteries seemed to be of normal calibre. The patient was put to bed, an alkaline diuretic mixture was ordered, and three times a day she had $\frac{1}{100}$th of a grain of nitro-glycerine in capsule form. On May 11th she reported a slight improvement in her sight. The œdema of the disc had passed off and its outline was clear, but the retinal œdema was more marked than formerly. The retinal veins had increased in fulness. By the 15th—that is, eight days from the onset of blindness—the disc and retina were free of œdema and the area of former pallor hardly differed in colour from the surrounding fundus. The cherry-red spot could be seen, but only faintly. The macular arteries seemed to be of good size, with blood flowing through them. On the 25th, the seventeenth day of the illness, vision equal to $\frac{6}{60}$ was obtained by tilting the eye upwards. The macula was still a little red, but the fundus was otherwise uniform in colour. The disc was sharply and clearly defined and its temporal half was pale in colour. The nitro-glycerine was stopped. On the 30th the pallor of the disc was more marked, the macular arteries were still of good size, and the macular region was normal in appearance. On August 5th there was distinct atrophy of the temporal side of the disc. The patient reported several attacks of momentary blindness of the right eye. On Nov. 3rd, 1899, the following note was made: "Vision equal to $\frac{6}{60}$, but clearer than formerly. Fixation of any point is accomplished by turning the eye upwards through about four or five degrees. In this way J. 20 is read. She is quite able, however, to direct her eye straight on an object, but she only sees the peripheral parts of it. The pupils are equal and equally active. She experiences no inconvenience and is unconscious of her defect unless she covers the left eye. During the last five weeks she has had four attacks of transitory blindness and on one occasion the left eye was slightly affected. The general fundus appearance is normal and the only indication of former trouble seen is the atrophied condition of the temporal side of the optic papilla, sharply separated by a vertical line from the rose-coloured nasal half. The scotoma in the field of vision has remained of constant size."

There can be no doubt that there occurred here a sudden and complete cessation of part of the retinal arterial circulation, and the typical appearance of the macula and the definite relationship borne by the ischæmic area to the course of the two branches of the macular artery clearly indicate it to have been the vessel affected. It is when we turn to the subjective symptoms that we meet with difficulty, for whereas the ophthalmoscopic appearance would lead us to expect in the field of vision an area of blindness having the shape of a **Y** lying horizontally with its base at the normal blind spot, there is found only an area corresponding to the macula and the part of the retina supplied by the terminal part of the inferior macular artery. In this connexion two cases reported by Clark of Columbus[3] are of much interest. In them it was the central retinal artery which suffered embolism, while the macular arteries—which were of deep origin, as in the present case—escaped. In each case, however, the area of remaining vision was triangular in shape with the apex at the point of fixation and the base to the temporal side—that is, roughly speaking, corresponding to the area of retina between the macula and the optic nerve entrance.

In seeking for an explanation of these apparent anomalies we must turn to the anatomy of the retinal circulation. With regard to the normal distribution of the arteries supplying the macular area one finds very varying statements, but the following shows the result of the examination of 100 eyes chosen indiscriminately. (The term "macular" artery is here used in reference to vessels which demonstrably reach the macular region and does not apply to the minute vessels which so commonly appear close to the margin of the optic disc and, passing horizontally outwards, seldom reach farther than half-way to the macula.) Macular arteries branch from the temporal arteries in 79 eyes; one macular artery branches from the central retinal artery in three eyes; one or both macular arteries appear near the margin of the disc in 15 eyes; and the common macular artery appears near the margin of the disc in three eyes. It is thus seen that most up to a large orange. One large cyst projecting outwards formed the bulk of the tumour. Its walls were made up partly of bony plates and partly of fibrous tissue, the interior being lined by a smooth, shiny membrane somewhat resembling the mucous membrane of the mouth. This large cyst communicated with other cysts, and across its cavity stretched fibrous bands, evidently the remains of a partition between it and some other cyst. The contents of the larger cysts resembled chocolate in colour and consistency, but in the smaller ones the fluid was clear and mucoid. The coronoid process of the jaw was hollowed out right up to its tip and the condyle was involved as far as the neck, so that it stood out like a button from the growth. The cut surface near the symphysis clearly showed that the growth originated in the central or cancellous portion of the jaw, distending the outer compact wall, and here was also some solid material which had not yet become cystic. The three teeth in the part removed were in the roof of a large cyst. On making sections of a small cyst which had thrown out a process I found that the cyst consisted of a wall of fibrous lamellæ lined on the inside by columnar epithelium. In the process of the cyst was more solid matter, and here I found masses of epithelial cells breaking down in the centre and forming cysts. In cysts of the size of a hazel-nut I found traces of epithelial lining, but in the largest cysts this had disappeared altogether. On the outside of the jaw near the teeth there was a solid portion of tissue which was made up of epithelium becoming cystic. An examination of the gum over the tumour showed that it was fairly normal, but at one point the epithelium showed signs of growing in. The tumour was therefore a multilocular cystic epithelial tumour.

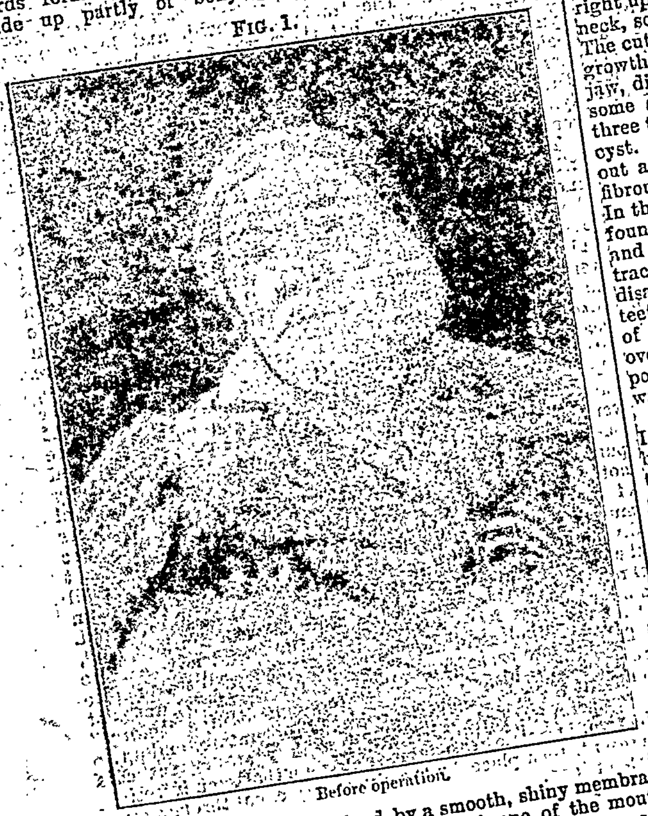
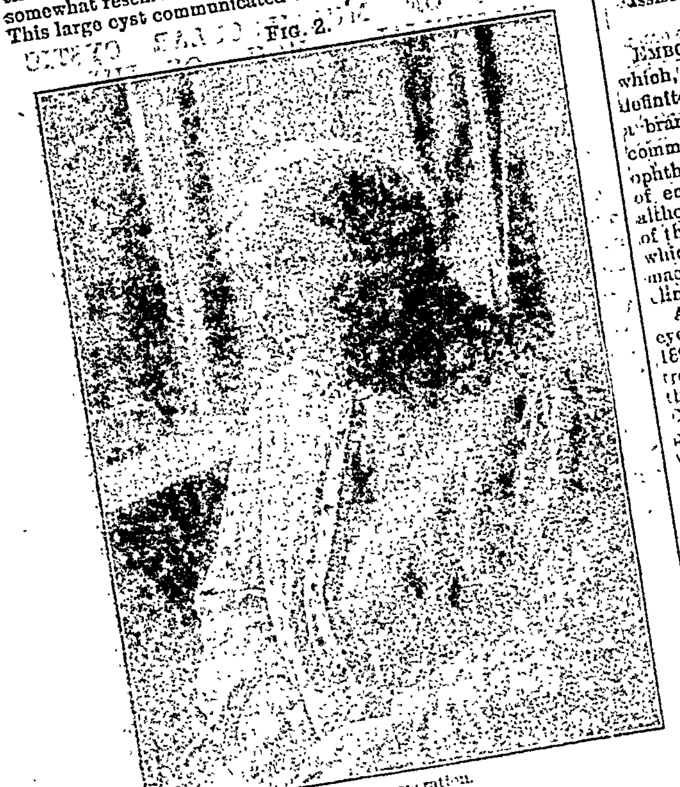
FIG. 1.



Before operation.

FIG. 2.



After operation.

After the gouging operation which I did on this case in 1897 I could find no traces of epithelium in the parts removed, but I had not at that time any of the solid portion of the tumour from the margin of the growth and I therefore drew erroneous conclusions concerning its nature. It was not until the growth had broken through the bony wall of the jaw that the increase in size took place. The tumour then became painful from pressure on surrounding parts setting up severe neuralgia; there was also some pressure on the pharynx and difficulty in taking food. As the tumour had lasted 20 years some idea of the slowness of its growth may be gained. I could get no history of tooth irritation at the commencement of the disease. The microscopical sections show every stage from the mass of epithelial cells to the fully developed cyst.

Liverpool.

AN UNUSUAL CASE OF EMBOLISM IN THE FUNDUS OCULI.

BY H. WRIGHT THOMSON, M.B., C.M. GLASG.,
ASSISTANT OPHTHALMIC SURGEON, GLASGOW ROYAL INFIRMARY.

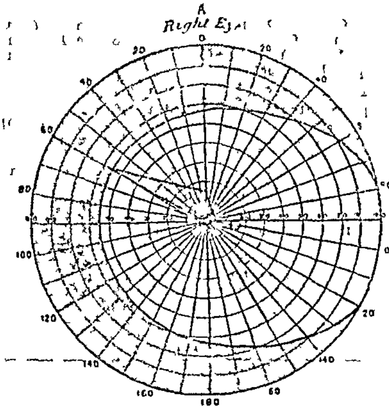
EMBOLISM of the central artery of the retina is a lesion which, though not very common, is well known and very definite in its symptomatology and sequelæ. Embolism of a branch of the retinal circulation is, however, a very uncommon affection, as borne out by reference to text-books on ophthalmology. Thus Berry mentions having seen one case of embolism of a branch of the central retinal artery, and although he does not state which branch it was the progress of the case would indicate that it was not the macular artery which was affected, and Schobl[1] refers to several cases of macular embolism reported by Perls as occurring in the clinic of Hirschberg.

A young woman, aged 19 years, first consulted me at the eye dispensary of the Glasgow Royal Infirmary on May 11th, 1899, but in view of the advantages likely to attend indoor treatment I referred her to the ophthalmic department of the infirmary, where she was admitted under the care of Dr. A. Maitland Ramsay, to whom my thanks are due for permission to follow out and publish the case. The history was that three days previously the patient had been sitting at the window of a room and after rising and going to a dim corner she noticed on looking towards the fire that the sight of the right eye had become very much obscured. Her movements had not been sudden, nor had she exerted herself in any way apart from rising and walking. There was no pain and the dimness of vision reached its maximum intensity instantaneously. She stated that for three years she had been troubled with attacks of transitory blindness of the right eye, occurring sometimes as often as two or three times a month. They were but momentary in duration and recovery was always sudden and complete. They bore no obvious relationship to menstruation. As a worker at a tobacco factory her eyes were not subjected to any great strain and they were noted to be almost emmetropic At the age of nine years she had suffered from chorea and on examination of the chest there was found a rough ventricular systolic aortic murmur well propagated into the carotids which were visibly pulsatile The urine cast an abundant sediment of urates There was a trace of albumin present and microscopically a few epithelial casts were seen Vision, as tested in the ordinary way, seemed reduced to perception of light, but on holding up a finger at a distance of one foot and directing the patient to look at the point she stated that she could not see the top part of it at all, but that the lower half was plainly visible Examination with the perimeter revealed an area of absolute blindness, as shown in the chart Owing to the limited area of the scotoma light perception in it was difficult to test accurately, but it certainly was much diminished, if not absolutely abolished On ophthalmoscopic examination the optic disc was found to be œdematous, with its margin except at the upper part, very indistinct On the outer side the disc seemed to merge into a pale, almost white, slightly œdematous area, of shape and extent as shown in Fig 2

---

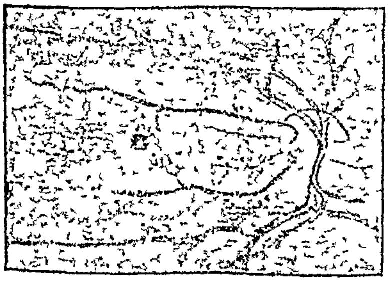
[1] Norris and Oliver's System of Ophthalmology.

FIG 1.



The shaded area extending out from the centre of the chart represents the area of blindness in the field of vision

FIG 2.



Appearance of fundus when first seen The area of lighter shading shows the extent of the ischæmia

There was a circular, cherry-red spot in the macula Its diameter was about one-fifth that of the disc and its deep red colour contrasted strongly with that of the normal fundus which extended right up to its temporal border The macular artery emerging from the optic disc at a spot near its lower and outer margin was seen to divide at once into two branches which, in comparison with those of the other eye, were small in size and embedded especially the upper, in œdematous exudation The retinal veins as a whole were distinctly engorged, while the arteries seemed to be of normal calibre The patient was put to bed, an alkaline diuretic mixture was ordered, and three times a day she had $\frac{1}{100}$th of a grain of nitro glycerine in capsule form On May 11th she reported a slight improvement in her sight The œdema of the disc had passed off and its outline was clear, but the retinal œdema was more marked than formerly The retinal veins had increased in fulness By the 16th—that is, eight days from the onset of blindness—the disc and retina were free of œdema and the area of former pallor hardly differed in colour from the surrounding fundus The cherry red spot could be seen, but only faintly The macular arteries seemed to be of good size, with blood flowing through them On the 25th, the seventeenth day of the illness, vision equal to $\frac{6}{36}$ was obtained by tilting the eye upwards The macula was still a little red, but the fundus was otherwise uniform in colour The disc was sharply and clearly defined and its temporal half was pale in colour The nitro glycerine was stopped On the 30th the pallor of the disc was more marked the macular arteries were still of good size, and the macular region was normal in appearance On August 5th there was distinct atrophy of the temporal side of the disc The patient reported several attacks of momentary blindness of the right eye On Nov 3rd, 1899, the following note was made "Vision equal to $\frac{6}{36}$, but clearer than formerly Fixation of any point is accomplished by turning the eye upwards through about four or five degrees In this way J 20 is read She is quite able, however, to direct her eye straight on an object, but she only sees the peripheral parts of it The pupils are equal and equally active She experiences no inconvenience and is unconscious of her defect unless she covers the left eye During the last five weeks she has had four attacks of transitory blindness and on one occasion the left eye was slightly affected The general fundus appearance is normal and the only indication of former trouble seen is the atrophied condition of the temporal side of the optic papilla, sharply separated by a vertical line from the rose-coloured nasal half The scotoma in the field of vision has remained of constant size "

There can be no doubt that there occurred here a sudden and complete cessation of part of the retinal arterial circulation, and the typical appearance of the macula and the definite relationship borne by the ischæmic area to the course of the two branches of the macular artery clearly indicate it to have been the vessel affected It is when we turn to the subjective symptoms that we meet with difficulty, for whereas the ophthalmoscopic appearance would lead us to expect in the field of vision an area of blindness having the shape of a **Y** lying horizontally with its base at the normal blind spot, there is found only an area corresponding to the macula and the part of the retina supplied by the terminal part of the inferior macular artery In this connexion two cases reported by Clark of Columbus[3] are of much interest In them it was the central retinal artery which suffered embolism, while the macular arteries—which were of deep origin as in the present case—escaped In each case however the area of remaining vision was triangular in shape with the apex at the point of fixation and the base to the temporal side—that is, roughly speaking, corresponding to the area of retina between the macula and the optic nerve entrance

In seeking for an explanation of these apparent anomalies we must turn to the anatomy of the retinal circulation With regard to the normal distribution of the arteries supplying the macular area one finds very varying statements but the following shows the result of the examination of 100 eyes chosen indiscriminately. (The term "macular" artery is here used in reference to vessels which demonstrably reach the macular region and does not apply to the minute vessels which so commonly appear close to the margin of the optic disc and passing horizontally outwards, seldom reach farther than half way to the macula.) Macular arteries branch from the temporal arteries in 79 eyes, one macular artery branches from the central retinal artery in three eyes one or both macular arteries appear near the margin of the disc in 15 eyes, and the common macular artery appears near the margin of the disc in three eyes It is thus seen that most commonly (79 per cent.) the macular arteries are offsets from the temporal branches of the central artery of the retina, but that in some cases (18 per cent.) they enter the fundus independently by an opening or openings in the optic disc near its temporal margin. Such marginal arteries are commonly called "cilio-retinal," and the recent anatomical researches of Elschnig,[3] who states their frequency at 7 per cent., go to prove that they always arise, directly or indirectly, from the circle of short ciliary arteries which surrounds the optic nerve.

---

[3] Ophthalmic Review, vol. xvii

When there is considered the great functional importance of the papillo-macular region and the infrequency of occurrence of cilio-retinal arteries it would seem not at all unlikely that in such cases there is present a supplemental arterial supply of retinal origin, ill developed, but capable of some extension when the necessity arises. If this be so, then in the present case the small branches of the central retinal artery have been sufficient to maintain the nutrition of all the area of retina affected, except the macula itself and a small strip extending downwards and outwards, till the re-establishment of the circulation in the vessel which had been temporarily occluded. The well-marked atrophy of the temporal side of the optic nerve shows that part to have been entirely dependent for nutrition on the cilio-retinal artery.

There will be noticed in the previous and subsequent history of the present case the frequent occurrence of attacks of transitory blindness of the right eye. Mauthner,[4] who had the opportunity of examining a patient while suffering from such an attack, found retinal ischæmia, and he explains the occurrence as being due to the temporary detention of a large embolus at the mouth of the central retinal artery, too large to enter, and soon carried on to enter a larger branch of the ophthalmic artery. Such an explanation seems readily applicable to this case, and all the more so that during the period of circulatory calm incident to hospital residence and treatment no such attacks manifested themselves. Further, it seems quite reasonable to suggest that the occlusion of the common macular artery was caused by the engagement at its origin in a ciliary artery of a large embolus which by the end of eight days was carried on to cause, it may be, embolism of a vessel freely supplied with anastomosis, and therefore giving rise to no gross symptoms.

To recapitulate, there occurred embolism of the common macular or cilio-retinal artery, the embolus being caught at its point of origin. Thus occlusion lasted eight days, during which time the nutrition of part of the retina involved was maintained by small branches of the central retinal artery and by the end of which time the embolus was carried further into the ciliary circulation.

Glasgow.

REPORT ON "HENPUYE" IN THE GOLD COAST COLONY.[1]

BY ALBERT J. CHALMERS, M.D. VICT., F.R.C.S. ENG.,
ASSISTANT COLONIAL SURGEON, ACCRA.

HENPUYE, or dog nose, is a disease frequently met with in the Gold Coast Colony and in certain portions of its Hinterland. The hideous deformity of the face which it causes is very striking to anyone who has lived in this part of West Africa. It is also known on the French Ivory Coast under the name of "goundu" or "anakhre," but "henpuye" is the native name (Appolonian) for the disease on the Gold Coast. The peculiar nature of the disease and the fact that, as far as I could find, very little was known as to its nature led me to make the inquiries which are now embodied in this report. I regret very much that I am unable to refer to original papers on the subject or to be certain that I have the full literature, but my excuse is that libraries do not exist in West Africa. The only references which I have met with are those mentioned in Dr. Patrick Manson's work on "Tropical Diseases" (page 594), and they are those of (1) Professor Alexander Macalister (Royal Irish Academy, 1882), (2) Surgeon J. J. Lamprey A.M.S., (*Brit. Med. Jour.*, vol. ii., 1887), (3) Dr. Henry Strachan (*Brit. Med. Jour.*, vol. i., 1894), and (4) Dr. Maclaud (Archives de Médecine Navale, 1895). It is by the kind permission of the Governor of this colony, Sir Frederick Hodgson, K.C.M.G., that I am allowed to publish this report. I am much indebted to Captain Armitage for his kindness in giving me information with regard to the different places in which he has noticed this disease in his travels, for drawing my attention to notes of the late Mr. Ferguson on the presence of the disease in Akim and Kwahu, and for making a painting of an advanced case of the disease; also to Dr. Henderson, the chief medical officer of the colony for many kind suggestion; and, lastly, to Mr. Crowther, draughtsman in the Public Works Department, for supplying me with a map of the colony and its Hinterland. The description of the disease will be divided into the following headings: (1) the General Description of the Disease; (2) the Description of Cases of the Disease; (3) the Treatment; (4) the Morbid Anatomy; (5) the Etiology; and (6) the Geographical Distribution.

THE GENERAL DESCRIPTION OF THE DISEASE.

Henpuye starts in a native of West Africa during or soon after an attack of yaws in which there is a history of the nasal mucous membrane being attacked as a small bony swelling symmetrically placed on either side of the nose. This swelling, which is generally oval with the long axis directed downwards and outwards, is attached to the nasal bones, the nasal process of the superior maxilla, and also to the superior maxilla in the more advanced cases. It is produced by the deposition of new bone under the periosteum on the external aspect of these bones and grows slowly in all directions. It in no way affects the mouth or the orbital or nasal cavities in any case which I have seen and the nasal ducts are quite unaffected. Rarely the growth is asymmetrical, being situated only on one side of the nose. Pain in the nose with the presence of a sore in that organ are the symptoms complained of at the commencement of the disease; later headache is sometimes felt and pain in the swelling during wet weather. As the growth becomes larger it seriously interferes with the sight by growing up in front of the eyes and even hiding them, but I have never seen it cause destruction of the eyeball (see Fig. 1). In

[1] Published by the permission of his Excellency Sir Frederick Hodgson, Governor of the Gold Coast Colony.

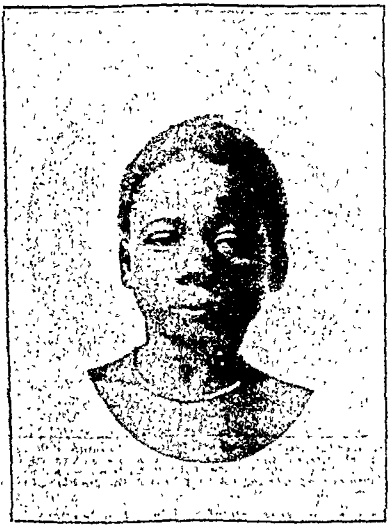
many cases the patient has to bend his head downwards in order to be able to see over the tops of the swellings. The skin over the tumour is normal and is freely moveable. The course of the disease is that the swellings may cease to grow at any period of their existence or may continue to grow for years—that is to say, they may remain quite small or may grow to be large lumps, in the latter case giving rise to the deformity and the interference with the sight, but I am unacquainted with any case in which they break down or ulcerate. Finally, the disease is much more common, in my experience, in men than in women.

DESCRIPTION OF CASES.

The following cases will be described: (1) slightly developed cases; (2) moderately developed cases; (3) an advanced case; and (4) an asymmetrical case.

Slightly developed cases.—CASE 1.—The patient, a boy of about 17 years of age, said that about seven years ago he noticed two small lumps on the nose which began after yaws in which there was a sore in the nose. They increased slightly in size, but soon ceased to grow and have been in their present condition for some years. He never felt any discomfort or pain in them. The two lumps had their long axes directed downwards and outwards, the measurements being half an inch by a quarter of an inch. They were attached to the nasal bones just above the cartilages and the nasal process of the superior maxilla and were firm, smooth, bony tumours. The skin over them was quite normal and they did not in any way project into the nasal cavity or affect the line of vision, being too small for the latter purpose. There was very little deformity and no treatment was necessary. In this case the lumps soon ceased to grow and caused little or no deformity.

FIG. 2.

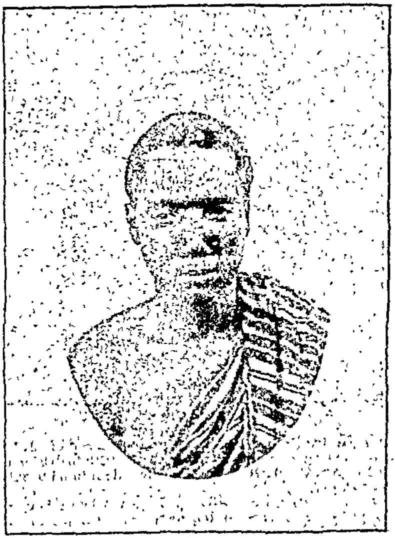


Representation of a slightly developed case (Case 2).

CASE 2.—A small Grunshi girl from Kumassi, about seven years of age, who had had yaws some time previously, felt pain in the nose a few months ago and noticed a small swelling on each side of the nose, and this gradually increased in size till it reached its present condition. Her mother was most anxious to have it removed on account of the deformity (see Fig. 2). On inspection there was found to be an oval swelling on each side of the nose attached to the nasal bones and the nasal process of the superior maxilla. The long axis of the swelling was directed downwards and outwards—an inch in length and half an inch in breadth. The nasal cartilages were not affected and the interior of the nose was normal. The orbital cavity, the mouth, and the nasal ducts were quite unaffected. The skin over the swelling was normal and freely moveable. The patient felt no pain in the tumour and she had never had any headache. The growths were removed by operation. It was very difficult to obtain definite history as to the time when this patient had had yaws and as to the time when the growth appeared, but as far as I could make out the yaws were well developed when the swelling was first noticed.

Moderately developed cases.—CASE 3.—A young man, a Ga native, who had had yaws about seven years ago, felt pain in the nose and got a person to look into the nose, who said that there were yaw spots on the mucosa and later a small swelling on each side of that organ was noticed. These small swellings grew slowly to their present size and the patient said that they were still increasing. He complained of frontal headache and of slight pain in the swellings in wet weather. On inspection (Figs. 3 and 4) two symmetrically placed swellings were seen on each side of the nose, looking somewhat like small eggs. They were oval in shape, with the long axis directed downwards and outwards. The left measured two inches by two inches and the right three inches by two and a half inches. A profile view showed that they were slightly concave on the side towards the orbit. They did not affect the orbital or nasal cavities, nor did they project into the mouth or affect the nasal ducts or the cartilages of the nose. They were attached to the nasal bones, the nasal process of the superior maxilla, and to the superior maxilla itself. They were smooth, but on the left side the tumour rose to a central ridge. The skin over the swellings was quite normal and was freely moveable. In order to see clearly the patient often had to bend his head somewhat. The growths were removed by operation.

FIG. 3.

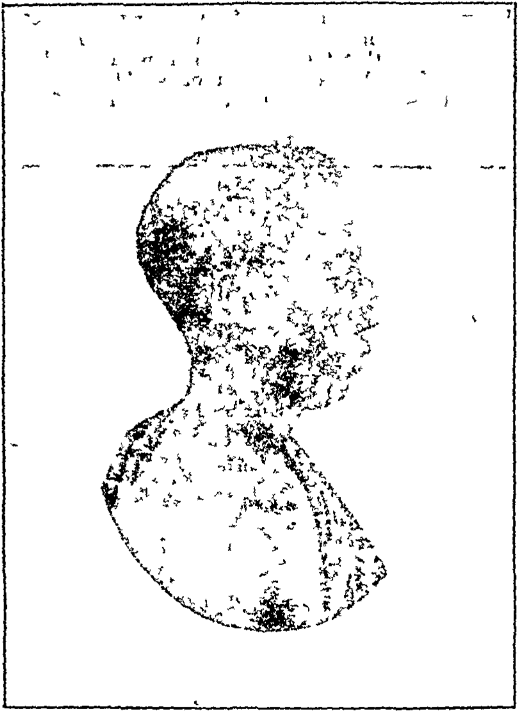


Full-face illustration of the disease as described in Case 3.

CASE 4.—The patient was an Akwapim woman, aged about 20 years. This case was similar to Case 3, but the swellings, which had started when the patient (who had suffered from yaws) was seven years of age, were rather more rounded. She would not consent to operation.

An advanced case.—CASE 5.—A man, a native of Appolonia, about 40 years of age, stated that the swellings began with pain in the nose after yaws when he was about six years old. They grew steadily and slowly till eight years ago when they stopped, and they have not increased in size since then. On inspection there were two oval swellings situated on each side of the nose, the left measuring two and a half inches by one inch and the right three quarters of an inch by half an inch. They projected upwards over the orbit, the long axis in each case being directed downwards and outwards. They did not project into the mouth, the nose, or the orbit, and the nasal duct was free. They were attached to the nasal bones, the nasal process of the superior maxilla, and to the maxilla itself. The skin over the tumour was normal and it was freely moveable. The patient complained of headache and found that the swellings interfered with his vision considerably, particularly on the left side. He refused to submit to operation.

FIG 4.



Representation in profile of the patient in Case 5

An asymmetrical case.—CASE 6.—An Ashanti boy, aged six years, from Donkeo Inquanta, had yaws and while suffering therefrom just a year previous to his consulting me the swelling appeared on one side of the nose, and had been growing ever since. There was no sign of any lump on the other side. He was advised to go to Kumassi for operation.

THE TREATMENT.

I have attempted to reduce these swellings by the administration of iodide of potassium but have *not* met with any success. The only treatment appears to be the removal by operation. The method I adopt is as follows. The eyes being protected by a pad over each an incision is made along the long axis of the tumour and the skin is freed on all sides so that its base is exposed. If the swelling is very small in a child it may be necessary to make a cross cut through the skin as well in order to get sufficient room to work in. The bone being exposed a portion of the swelling can easily be cut away by bone forceps because it is very soft. If large a few nicks with a Hey's saw are found most useful in enabling a large portion of the mass to be removed entire. After as much has been removed as is possible with the bone forceps more may be got away by means of the gouge or the gouge forceps or the nibbling forceps. I have experienced difficulty in removing the deeper portions, particularly those close to the orbit. I need hardly say that in the latter the eye has to be carefully guarded from injury. After removal of the bone the wound is well washed out with an antiseptic lotion. The bleeding is slight and is easily controlled by pressure. The wound is closed by a continuous suture and it heals up readily.

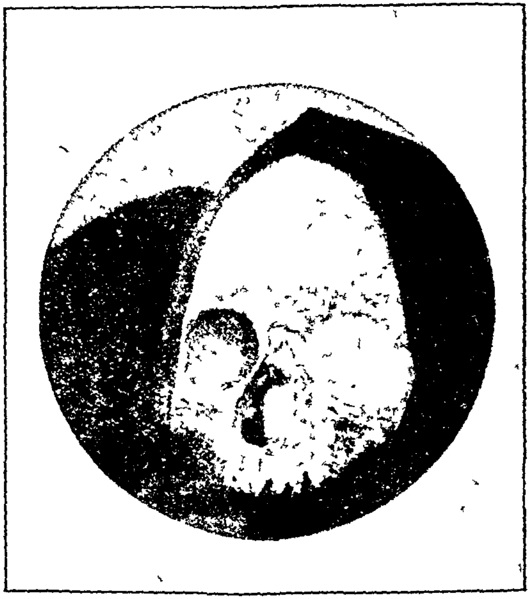
THE MORBID ANATOMY.

I have never had any chance of examining the growth post mortem, but the portions which I have removed *en masse* by operation have enabled me to make some investigations. The periosteum strips off readily and under this is a thin shell of compact bone which appears somewhat ridged on the side towards the periosteum. The rest of the tumour consists of cancellous bone. The whole swelling cuts readily with bone forceps and consists of quite soft bone. On making microscopical preparations there were signs of ossification in membrane proceeding under the periosteum and the rest appeared like ordinary wide-meshed cancellous bone. The whole process appeared to be that of a slow "osteoplastic periostitis."

ETIOLOGY.

Two views on the etiology of this disease have been brought forward up to the present time, as far as I know—viz., that the swellings were of a racial character and that the process was started by the larva of some insect. With regard to the first I have only to mention that the disease is found in Ashantis, Grunshis, Fantees, Abartas, the Ga people, &c., &c., races quite different from one another, to show that this cannot be entertained. As to the second I have never met with evidence which would support the idea that the disease was started by a larva. On the other hand there is always the history of yaws and of the tumour starting during the attack of yaws—i.e., during the period of eruption or soon after. Then, again, the patients complain of pain in the nose with, in some cases, distinct history of a sore and sometimes discharge preceding the swelling. This might be due to some irritation or ulceration of the nasal mucous membrane by the yaws. I have never had the opportunity of examining any person at this stage of the disease, but in the more developed cases I have examined the nose for marks or signs of old ulceration but have not found them. If, however, the nasal process of the superior maxilla be examined (Fig. 5) a few foramina are to be seen, and these are often joined together by a small groove indicating the position of a bygone suture. The foramina are for small blood-vessels which are said to communicate with those of the mucosa of the nose. The site of these foramina is the situation where henpuye starts and I venture to bring forward the theory that the causation of this peculiar disease is due to an osteoplastic periostitis brought about by the absorption of the poison of yaws from

FIG. 5.



From a photograph of a Moshi skull, to show the suture of the nasal process of the superior maxilla, with a hair passed from the nose through one of the channels for vessels, a little of the bone being cut away to show the direction of the canal.

the nasal mucous membrane through the small vessels (or lymphatics) keeping open the foramina which indicate the suture above mentioned

THE GEOGRAPHICAL DISTRIBUTION

I am only aware of cases reported from the Gold and Ivory Coasts of West Africa and the West Indies I never met with it in Mamprusia, nor have I met any trader coming from Moshi with it nor have I met with it in Fra Fra, and I can find no one who has seen it in the eastern parts of the colony But in the following districts it has been noted · Ahanta, Appolonia, Fantee, Accra, Aquapim, Akim, Assin, Sefwhi, Ashanti, Attabubu Kwahu, Kintampo, Berekum, Gaman, the Neutral Zone and Wassaw It is perhaps most common in the Sefwhi Wassaw, and Appolonia districts which adjoin the French Ivory Coast where cases are also known

I look upon henpuye as a localised osteoplastic periostitis in the region of the nasal process of the superior maxilla, generally symmetrical, due to yaws and found among the natives of West Africa and the negroes of the West Indies

Accra

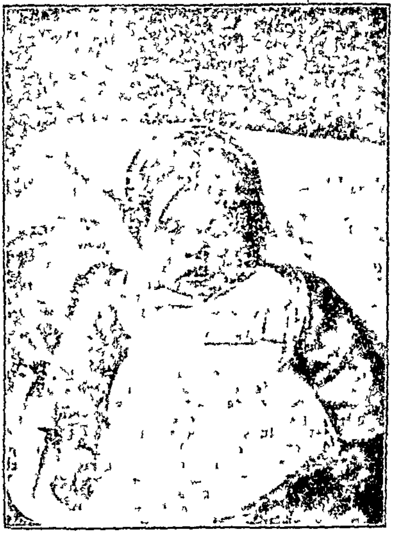
THE DIFFERENTIAL DIAGNOSIS OF MONGOLISM AND CRETINISM IN INFANCY

By G A SUTHERLAND, M D EDIN,
PHYSICIAN TO PADDINGTON-GREEN CHILDREN'S HOSPITAL ASSISTANT PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL

UNDER the term "cretinoid" have been included various forms of imbecility in infants which until recent years were not clearly differentiated as to their pathology and characteristic features In practice we find that children of the cretinoid type are either cretins or Mongolian imbeciles Cretinism, or infantile myxœdema, is a rare affection in this country, but in the medical literature of the past few years, owing to the successful employment of the thyroid gland treatment, many cases have been reported Mongolism is a form of congenital imbecility which is much more common but to which comparatively little attention has been directed It is so named from certain facial appearances which at first sight suggest a Chinese origin The term was introduced by Dr Langdon Down in his classification of idiots on an ethnological basis, and although his classification has not been generally accepted the name "Mongolian" has been adopted as happily descriptive This form of imbecility is well known to those engaged in asylum practice, but it is during the early months of life that diagnosis is called for and treatment must be adopted if those fragile lives are to be prolonged

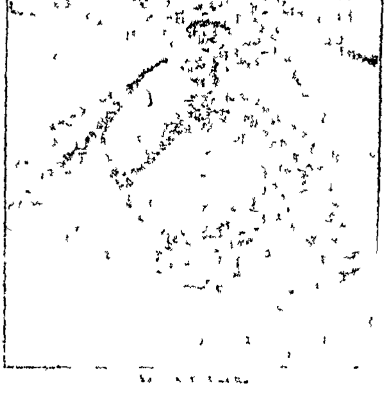
Owing to the similarities between these two affections, "cretinism" and "Mongolism" which are at first sight very striking, confusion is apt to arise In both the physical and mental development is delayed, the vital powers are low, the temperature is subnormal, and sensitiveness to cold is a marked feature In both occur the following facial alterations—viz, depressed bridge of the nose, small palpebral fissure, and protruding tongue In both the abdomen is large, an umbilical hernia is often present, and there is a marked tendency to constipation In both the fontanelle is late in closing and the teeth are late in appearing, are poorly developed, and decay rapidly. In both speech is much delayed and is replaced by peculiar, grunting, animal-like noises, while snoring during sleep is very pronounced In both there is great muscular debility without any definite paralysis Hence it may happen that a case of Mongolism is regarded as one of cretinism, thyroid treatment is adopted and this failing to [illegible] the treatment is rather discredited in the eyes of the physician If, instead of comparing and contrasting a typical case of Mongolism (Fig 1) with one of cretinism (Fig 2) we find that the differences are great and [illegible]

FIG 1



A case of Mongolian imbecility

FIG 2.



[illegible]

In the following table I have enumerated some of these differences:—

CRETINISM.	MONGOLISM.
1. Characteristic features seldom present before the sixth month.	1. *Present at birth.*
2. Dull, impassive infants, taking no notice of anything or anyone; *face expressionless, of a lower animal type, "toad like"*; absence of active movements.	2. Smiling, grimacing infants; shy, but observant, imitative, *active movements present.*
3. The skin swollen, dry, scaly; fatty deposits in neck, hair coarse and scanty.	3. These changes absent.
4. No characteristic skull changes.	4. *The skull flattened antero-posteriorly, brachycephalic.*
5. The palpebral fissure *appears* small from swelling of eyelids; epicanthus not present.	5. The palpebral fissure *is* small and obliquely placed, without swelling of lids; epicanthus marked.
6. The *tongue is very large, swollen, and protruding.*	6. The *tongue is large, often protruded, but not swollen.*
7. The lips are thick, immobile, and everted.	7. The lips are mobile, pursed up, and everted on movement or crying.
8. *Congenital heart disease rare.*	8. *Common.*
9. Relative size of fingers normal.	9. Little finger short and curved; thumb short.
10. Thyroid gland absent or atrophied.	10. Thyroid gland normal.
11. *Marked benefit received from thyroid gland treatment.*	11. No benefit.

In well-marked cases these differences will usually allow of an exact diagnosis being made, but as in other affections one not infrequently meets with slightly marked cases in which the symptoms are not pronounced, and many of them may be absent. In such a case the special Mongolian characteristics on which stress should be laid are the active movements of the face and limbs as contrasted with the lethargic state and expressionless face of the cretin. The smiling face of the Mongolian imbecile suggests the possession of some secret source of joy, while the somewhat sad countenance of the cretin suggests the cherishing of a secret sorrow. A careful investigation as to anatomical defects and changes will usually reveal the presence of some of these which are sufficiently characteristic. *The final test is the therapeutic one, as under the administration of thyroid gland the cretin will in time show changes of a most striking character while the Mongolian infant will remain unaffected.*

BULLET WOUND IN THE HEAD; REMOVAL OF THE BULLET FROM THE NOSE TWENTY MONTHS AFTERWARDS.

By CLAUD WOAKES, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE LONDON THROAT HOSPITAL; AURAL ASSISTANT AT THE LONDON HOSPITAL.

A MAN, aged 24 years, late a private soldier, presented himself on June 14th, 1899, at the aural department of the London Hospital, complaining of a foul-smelling discharge from the left nostril. He gave the following history. On Oct. 20th, 1897, he was one of those engaged in the brilliant attack on, and capture of, the Dargai heights when he was shot from above, the bullet entering the skull just below the left frontal eminence. He became unconscious, but recovering quickly was able to retire and receive first aid. The superficial wound in the forehead was stitched up. At the same time he expectorated a small piece of lead. He was sent to the base hospital, where his left eye, through which the bullet had passed, was removed. On examining the left nostril I found it to be almost closed by a broad bridge of mucous membrane running from the outer wall to the septum. After cutting through this under cocaine an examination of the interior of the nostril with a probe revealed a hard partially moveable substance buried in granulation tissue. This examination causing some hæmorrhage an antiseptic and astringent lotion was prescribed and the patient was told to come again in the following week. On June 21st a clearer view was obtained, and by seizing the hard substance with a pair of strong nasal forceps passed up the nostril a large irregular piece of lead was removed without injuring the nostril, with a square inch of khaki attached which had been carried in with the bullet from the peak of the helmet, the whole being covered with foul smelling crusts and discharge. The hæmorrhage caused by this operation was easily stopped by syringing with hot antiseptic lotion, which the patient was ordered to continue to use for a week, during which time several pieces of bone came away. Besides the discharge before mentioned the symptoms had been severe headaches and slight attacks of ague, but when the patient was last seen, five months after the removal of the bullet, these symptoms had all disappeared. In the accompanying illustration the bullet is represented as slightly smaller than its actual size. It measures one inch in length, five-eighths of an inch in breadth, and three eighths of an inch in width, and it weighs 343 grains. The patient has now a large depressed scar over the left frontal eminence and eyebrow. The left eye is entirely gone, the left antrum is minus its nasal wall, and the anterior two-thirds of the inferior turbinated bone are absent, and there is a small stellate cicatrix in the roof of the mouth slightly to the left of the middle line.

Harley street, W.

CASE OF IMPACTED EXTRACAPSULAR FRACTURE OF THE NECK OF THE FEMUR.

By H. E. BELCHER, L.R.C.P. LOND., M.R.C.S. ENG.

A MAN, aged 26 years, was driving at about 10 A.M. on Dec. 7th, 1899, when the horse bolted and threw him into the road. He had been a heavy spirit-drinker for months, and when I saw him, immediately after the accident, he appeared to be suffering from the effects of drink and of a blow which he had sustained on his head. His right temple was cut and bruised, a branch of the temporal artery was exposed and bleeding, and his right leg lay in the everted position, but no other signs of injury were apparent. On trying to get him into a cart he would not allow us to bend his right hip. Examining him at home I could detect a swelling of the upper third of the right thigh, which he could not bear to have flexed. There was no apparent shortening, nor could I discern any crepitus, nor was there any apparent bruising of the hip. He complained of great pain all down the front of the thigh to the patella, and he had also considerable erectio penis. Next day the swelling had subsided and he felt better, but could still lift the leg only by the help of the sound one. The leg lay everted and on very careful measurement showed about half an inch of shortening. During the afternoon of this day he had two attacks of urgent dyspnœa, which I attributed to his former drinking habits, and in the evening he became violently delirious, sat up, bent his hip, and attempted to walk. During some of the movements I tried to discover any crepitus, but failed. The next day the swelling of the thigh had returned, no greater shortening could be made out, or crepitus, and during the night he died. After death the right lower limb was found to be very evidently shortened by about three inches, and the right thigh appeared to be much broadened out. By using force I was able to undo the impaction and I found the seat of fracture quite at the root of the femoral neck.

The chief points of interest to me and those with which I was not absolutely familiar were the very slight amount of shortening which could be discerned and the absence of *any evidence of severe bruising of the hip.* The characteristic eversion of the foot, the broadened appearance of the thigh, and the helplessness of the limb were the chief signs of injury.

THE ORCHITIS OF MUMPS.

BY CLEMENT DUKES, M.D. LOND.,

PHYSICIAN TO RUGBY [illegible] AND SENIOR PHYSICIAN TO RUG [illegible] OSPITAL.

IN the elucidation of facts with regard to diseases it behoves us to be careful that our facts are real and universal and not subject to the alteration of time and circumstances. By virtue of a very long experience, dating from April, 1871, I have from time to time discussed the question of the orchitis of mumps. I have emphasised these supposed *facts*: (1) *that the orchitis of mumps is not a metastasis*; (2) that it almost invariably occurs on the seventh or eighth day of mumps, though occasionally mumps commences with orchitis on the first day, when it may occasion very alarming symptoms; (3) that it never arises before puberty; and (4) that it does not occur after puberty if the patient be kept in bed over the eighth day.

We have just passed through an epidemic of 30 cases of mumps at Rugby which indicates that my previous experience of the orchitis of mumps was inaccurate when applied over a long series of cases extending over many years, for this series of cases belies all my former ones.

No. of case.	Residence.	Mumps.	Date.	Orchitis.	Date.	Day of orchitis from mumps.
1	G. S.	Right parotid.	Oct. 27, 1899.	Right.	Nov. 3	Seventh day.
2	"	"	Nov. 13, 1899.	"	" 21	Eighth "
3	P. S.	Both parotids.	Nov. 15, 1899	"	" 20	Fifth "
4	G. S.	Left parotid.	Nov. 16, 1899.	Left.	" 23	Seventh "
5	P. S.	Right "	Dec. 6, 1899	Right.	Dec 9	Third "
6	S. W.	Left "	Dec. 5, 1899.	Left.	" 11	Sixth "

Here, therefore, we have these facts—that out of 30 cases of *mumps 20 per cent. developed orchitis, although not one* of the boys moved from his bed for any purpose whatever for eight days; also the days on which the orchitis showed itself varied between the third and the eighth days, which is quite a new experience to me.

Rugby.

A BOY'S EAR BITTEN OFF BY A HORSE.

BY JOHN MUNRO MOIR, M.D. ABERD.

IN THE LANCET of Dec. 2nd, 1899 (p. 1572), Mr. E. W. Cuming asks for information regarding any cases of the above accident. The following case may prove of some interest to him.

A few years ago I was called to attend the son of a patient of mine who while grooming his father's horse, or rather small pony, had one of his ears completely bitten off, quite as cleanly and neatly as if a surgeon had done it with a knife. *The whole of the structure of the external ear* was removed and was intact. It was some time after the accident before *I saw the boy*—I should say about two hours. The ear, which had been carefully preserved was cold and shrivelled up, and I regret that I did not adopt the treatment mentioned in the case referred to in THE LANCET of June 4th, 1898 (p. 1533), with such a successful result—viz.; that of sewing on the severed ear. I thought that in my case there would be but little chance of union owing to the length of time elapsing from the occurrence of the accident until I saw the boy, but this will not *deter me from doing so should I see another case.* The disfigurement resulting from this accident is very marked; the organ *is* a very difficult one to model artificially, and even were this *done successfully* it would be difficult to attach it and keep it in position. Fortunately, as pointed out by Mr. E. W. Cuming, these accidents are rare.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF SUPPRESSION OF URINE ASSOCIATED WITH A SINGLE KIDNEY.

(Under the care of Mr. D'ARCY POWER.)

FOR the notes of the case we are indebted to Mr. Percival Wood, house surgeon, and Mr. H. P. Johnson, dresser of the case.

A man, aged 36 years, was admitted into St. Bartholomew's Hospital on the evening of Saturday, August 26th, 1899, vomiting and saying that he had total suppression of urine. The patient stated that he had been in his usual health until Sunday, August 20th, when he passed no urine all day. He was not inconvenienced in any way and went to his work as usual on the Monday and afterwards had a bicycle ride. On the Tuesday he still felt in excellent health and went to his work, though he still passed no urine. On the Wednesday he did not feel well and stayed at home. On the Thursday he began to feel weak and to vomit and his condition became gradually worse until his admission to the hospital on the Saturday. He then had a slight headache and a little giddiness but "beyond the vomiting and weakness he did not feel much wrong." He had seen a medical man frequently during the week who passed catheters, but he had "not passed more than half an eggcupful of urine the whole week." His bowels were opened every day but only slightly. There was nothing of importance in his history He had never had any abdominal pain suggestive of renal colic or any difficulty in passing urine. *His urine had never contained gravel, blood, or sediment.*

When the patient walked into the surgery he looked ill, his face was drawn, and he was very sallow. His skin was moist and his breath was foul, but there was no urinous odour about him. He was evidently very weak, but he did not seem to be giddy. He could see quite well and the pupils were equal and contracted. The pulse was very soft and was regular both in strength and frequency, beating 84 to the minute The legs pitted slightly on pressure. The abdomen moved well. It was neither distended nor tender and except for a slight dulness in the right loin it was everywhere resonant. No tumour could be felt either in the bladder or the kidney region, the only abnormality being a slight muscular rigidity on the right flank. The heart and lungs were apparently normal, the respirations being 12 or 14 a minute. The face was not puffy anywhere; the tongue was dry and somewhat cracked. One eye was examined under atropine with the ophthalmoscope The edge of the disc was slightly blurred, but otherwise the retina was normal.

A catheter (No. 10) was passed and went easily into the bladder; no urine was withdrawn. A sound was also introduced, but nothing was discovered. The diagnosis of obstructive suppression was made and the patient was therefore admitted to a surgical ward, an opinion being further hazarded that the patient had only one kidney. Mr. D'Arcy Power saw the patient about two hours later and determined to explore the right kidney, being guided to this side by the muscular rigidity in the right flank. An incision was made in the right loin and a small contracted kidney was found lying high up under cover of the eleventh and twelfth ribs. The capsule was torn through, the pelvis of the kidney was explored with the finger and a needle was driven through the cortex in several places, but no stone was felt and the ureter was manifestly free from obstruction. The wound was accordingly closed and dressed, and when the patient recovered consciousness three hours later he appeared to be in the same condition as he was before the operation, being quite sensible, rather thirsty, quiet, and without pain or discomfort. On the next morning he was ordered a hot air bath at a temperature of 105°F., and almost immediately afterwards he passed voluntarily about three ounces of blood-stained urine. An hour later he passed another two ounces of urine, but shortly afterwards he became very restless and cyanosed, whilst his pulse began to intermit. This attack passed off after three minims of liquor strychniæ had been injected and half an ounce of brandy with water had been given by the mouth, and he had been made to inhale oxygen. He improved so much that his wife who was talking to him said it was difficult to understand that he was at all ill, but an hour later he vomited about half a pint of clear fluid, again became restless, and died in five minutes, remaining conscious and answering questions to within three minutes of the end.

Necropsy.—The post-mortem examination showed that both lungs were very œdematous and congested, and that both pleural cavities contained fluid. The peritoneal cavity contained about four ounces of serous fluid and there were several firm adhesions on the right lateral aspect of the liver, apparently caused by old perihepatitis. The left kidney was represented by a small thin piece of fibrous tissue of about the size and shape of a flattened horse bean. The left ureter was small, but was present in its whole extent and was patent throughout its course. The left suprarenal capsule was normal and received a small vessel direct from the aorta. There was neither renal artery nor renal vein on the left side. The right kidney was somewhat smaller than usual and its pelvis was dilated. The capsule was adherent and on section the renal substance was seen to be granular and congested. The recesses of the pelvis contained four small pigmented calculi, the largest being smaller than a grey pea. The ureter was quite free in its whole course and the suprarenal was healthy.

Remarks by MR. D'ARCY POWER.—The patient died from suppression of urine, the result, I suppose, of his single kidney striking work owing to the irritation of the calculi it contained. It is creditable to those who first saw him that the exact cause of the condition should have been diagnosed, though it is true that they are not entitled to the whole credit, for only a few days previously one of my colleagues had a similar case in which the single kidney was of the large white variety, whilst in the present instance it was small and contracted. The clinical history of the patient, so often wanting or imperfect, is unusually full and shows how little inconvenience was produced by the condition. The absence of the renal artery and vein shows that the left kidney was congenitally absent.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A CASE OF SUPRAPUBIC LITHOTOMY; REMOVAL OF TWO VESICAL CALCULI; RECOVERY.

(Under the care of Mr. T. VINCENT JACKSON.)

MANY considerations influence the answer to the question, What is the best method of removing a stone from the urinary bladder? The mortality resulting from the operation itself will naturally vary with the skill and experience of the operator whatever may be the operation performed. Of recent years so few cases of lateral lithotomy have been performed that no extensive statistics are obtainable; perhaps the best statistics of the operation of lateral lithotomy are those collected by Mr. C. Williams and founded on the cases at the Norfolk and Norwich Hospital. From 1772 to 1839 there were 871 lateral lithotomies at that institution and of these 116 patients died; this is a death-rate of 13·32 per cent. In boys the results were better still, for between the ages of five and 10 years there was a mortality of less than 4 per cent. It is probable that more modern statistics of lithotomy would show some improvement on these results, but it is unlikely that the mortality would be less than half of that exhibited in the Norwich statistics. The mortality of the modern operation of litholapaxy may be gauged from the following statistics Mr. R. Harrison[1] performed 101 lithotrities from 1890 to 1897 and had six deaths—i.e., a little less than 6 per cent. Major R. Baker, I.M.S., has published[2] notes of 404 cases of litholapaxy which he performed in India. The mortality was under ½ per cent. It will thus be seen that the mortality in litholapaxy, though liable to vary, is certainly less than in lateral lithotomy. The percentage of recurrence after the crushing operation is higher than after lateral lithotomy, but with a very much lower mortality this is not of great importance. The results of the high operation of lithotomy also vary. Freyer, in a discussion at the Harveian Society that followed a paper on litholapaxy, said that suprapubic lithotomy in children had a mortality of 20 per cent.,[3] but this cannot be accepted as a representation of the danger of the high operation in general. Witte[4] had 32 cases of suprapubic lithotomy and four died, a mortality of 12·5 per cent. Lissjanski[5] had only one death in 18 cases, that is a death-rate of 5·5 per cent. The large size of the stone is generally considered to point to the desirability of performing lithotomy, but Milton[6] has said: "The larger the stone and the more exhausted the patient, the greater is the indication for lithotrity." In boys every method gives more favourable results than in men, but there is still much difference of opinion as to the most suitable operation. Mr. Jackson's interesting case is a very good example of the good results which may be obtained by the high operation.

A boy, aged eight years, was admitted into the Wolverhampton and Staffordshire General Hospital on July 19th, 1899, having been sent by Mr. A. T. Wills of Brewood. The history was very incomplete and indefinite; a family tendency was denied and only recent symptoms were mentioned such as frequent and painful micturition (day and night), the pain being referred to the end of the penis. Exercise added to the pain and produced a wish to defæcate. Upon examination the child was seen to be proportionately small for his age and spare of habit; indeed, he was a weakly and delicate-looking boy. The penis was small; the prepuce was long and its free margin was much reddened and thickened. The meatus urinarius and the capacity of the urethra were small. No hernia existed. Under chloroform a sound equal to a No. 3 catheter was inserted into the bladder, but it encountered a difficulty at the neck as if a stone projected. This was so, and it appeared to be of some size. The exploration with the sound was supplemented by the forefinger within the rectum and by a hand placed on the hypogastric region. The patient was admitted into the children's ward and his health and his diet were carefully attended to.

On July 29th under chloroform suprapubic lithotomy was performed. No rectal plug was used, but the bladder, first emptied of urine and carefully washed out, was distended with warm water. As the soft catheter was withdrawn the root of the penis was tied with tape. The bladder was opened above the symphysis pubis by cutting down to and into it. On the left forefinger being introduced two calculi were felt. One was almost free, except that its distal (spiked) end projected into what appeared to be the vesical end of the urethra; the second calculus, behind and somewhat under it, was lying in a pouch. Both were removed by a small pair of forceps and when placed together the measurements were one inch by one and a half inches. The sides of the bladder wound were approximated and so retained by Mr. H. D. O'Sullivan (the house surgeon) and then carefully stitched together, 12 fine silk sutures being inserted—six deeply and six superficially. The layers of the abdominal wall were closed separately by silk sutures; the wound was protected and sealed by a thick layer of cotton-wool and collodion, which was not changed for a week. A soft catheter was passed and retained in the bladder. It is unnecessary to encumber this report by recording the daily notes as the progress was uneventful The cutaneous portion of the wound slightly re opened and four silk sutures, being loose were removed On Sept 8th the boy was sent home perfectly recovered

[6] Moscow International Medical Congress.

Remarks by MR JACKSON —This case is reported as a contribution to the treatment of vesical calculi in properly selected cases in male children by suprapubic lithotomy indeed, it is the first child on whom I have so operated If the stone is of small or even of moderate size and the age of the patient and the capacity of the urethra will permit, the case being uncomplicated, lithotrity is no doubt an excellent means of cure, but the case recorded belongs to another category and a different surgical proceeding was called for and successfully employed If called upon to repeat this operation and the condition is favourable for closing the wound I shall not stitch together the abdominal wall layer by layer but close it by silkworm gut

Every now and then a discussion arises in the medical journals as to the preferable operation — lithotomy or lithotrity—for the removal of stone from the bladder of boys In reading these discussions and the opinions expressed I have been struck by the rather too dogmatic and *doctrinaire* tone adopted by those who so strongly and almost as partisans advocate the modern method of treating stone in the bladder (lithotrity) I fail to see that it is possible for any one method, modern or otherwise to be equal or sufficient to the varying conditions met with in infants—and shall I also add octogenarians—who may be the unfortunate sufferers from such a painful distressing, and destructive malady as vesical stone

The great promoter and supporter of lithotrity in this country, Sir Henry Thompson skilful and successful as he has ever been never held the cramped opinion that lithotrity had superseded lithotomy and that the performance of the latter instead of the former was ' retrograde ' old fashioned,' "eccentric,' and 'out of place I plead for the permissive right of an operating surgeon to be allowed to select what in his judgment is the best and the most likely operation to be successful in any given case under his care There ought not to be and there cannot be, a hard and fast line in surgical treatment for much of that must depend on individual experience Mr Reginald Harrison in the Bradshaw Lecture (1896) dissents from the tendency existing at the present day to relegate lateral cystotomy to the surgical shelf Lithotrity is a very easy operation lateral lithotomy is not and without saying that lithotomy is boycotted on account of its difficulty I feel that it still holds a place in the art of surgery and its employment for the removal of suitably sized calculi in very young male children is not only a safe but a successful preferable and complete procedure

I desire to thank Mr H D O Sullivan and charge nurse Middlemist for their post operation supervision care and attention

Medical Societies

EDINBURGH MEDICO CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens

A MEETING of this society was held on Dec 20th and was devoted to the exhibition of patients and specimens, Mr A G MILLER the President being in the chair

DR ALEXANDER BRUCE showed 1 A case of Infantile Paralysis affecting the muscles of the left hand The patient was a girl, aged 19 years and the history given was that when she was a child a few weeks old she received a stroke on the back of the left hand and that soon afterwards the hand was noticed to be paralysed Her present condition showed that the left hand was much smaller than the right and that every intrinsic muscle of the hand was atrophied The muscles of the forearm were normal and there was no sensory disturbance The lesion had apparently affected the first dorsal segment of the cord and the history given was deceptive in that the case was one of infantile paralysis 2 A case of Progressive Muscular Atrophy of the Peroneal or Charcot Marie type This case differed from the ordinary type in that there were no evidence of the disease occurring in the other members of the patient's family or ancestors (she was a woman past middle age) in that the patient was rather beyond the age at which the disease usually appeared and in the fact that the trunk muscles were beginning to be affected also The paralysis began after pain in the legs and now there were drop ankle and contracture but no sensory disturbance The peroneal muscles were atrophied The hands became affected later and now showed the well marked claw character with some ulnar flexion The forearm was somewhat atrophied and there was some spinal curvature The lower lip was relaxed and there was some deficiency in articulation It was a purely muscular paralysis and at an early period the reflexes underwent diminution The affection was evidently a parenchymatous neuritis spreading centrally to the posterior columns of the cord 3 A case of Senile Chorea (exhibited for Dr J O Affleck) in a game keeper who until he fractured his leg eight years ago was perfectly healthy A year after the accident a chorea manifested itself It affected the head as well as the rest of the body There was no symmetry or rhythm in the movements and the patient had difficulty in speaking on account of the choreic movements of the tongue and lips 4 A case of what might be called Huntington s Chorea but which Dr Bruce thought was a true and typical Convulsive Tremor, though some might say that it was due to *hysteria* The patient a man, had syphilis five years ago and two years subsequently the affection began by a difficulty in standing and now there was a peculiar condition of tremor which affected chiefly the thighs and calves In the upper extremity shrugging movements of the shoulders were visible In the legs sharp jerking movements were seen, and rapid flexions and extensions of the feet took place On lying down the legs were jerked upwards at the thighs and rotation at the hip joints was noted There was no anæsthesia The toes underwent flexion and extension, as did also the thumbs to a less extent All these movements were less marked when the patient walked, or during sleep or when he was at perfect rest and were aggravated when he was excited There was great hyperæsthesia in the muscles By tapping over each it could almost always be made to contract The patient s memory was not so good as it had been Dr Bruce did not think that it was a case of hysteria 5 A case of Injury to the Lumbo sacral Nerve roots The patient was a young man who fell downstairs and injured his left hip Two days after the accident his left limb became powerless and in three weeks it was anæsthetic The lesion seemed to affect the first and second sacral roots and as the bladder and rectum acted well it was thought that the other sacral roots must be intact The injury must have affected the roots of the cauda equina on one side Dr Bruce pointed out the areas of motor and sensory paralysis and noted that the case was complicated by the fact that after the patient left the hospital after the accident he imbibed freely of alcohol and so superimposed on the traumatic an alcoholic neuritis

DR NORMAN WALKER exhibited 1 A man suffering from the rare condition of Acne Necrotica or acne varioliformis as it is sometimes called from the scarring The only resemblance which this affection bore to ordinary acne was that it occupied similar seats It was a necrosis of the whole skin and bore no evidence of a syphilitic cause, Dr Walker believed 2 Two cases of Ichthyosis in the same family 3 Cases treated by the X Rays Dr Walker had only employed this treatment in those cases of skin disease where he deemed that it would be most likely to do good—as, for example in cases of lupus and favus These rays caused complete loss of hair which re-grew later One of the cases shown was that of a girl who had suffered from favus for 10 years and had undergone repeated treatment She was first treated by the x rays in the spring of 1899 and now the head was quite free from disease Dr Walker showed three cases of lupus which had been treated thus and which were very greatly improved 4 A case of Leprosy in a young man (exhibited for Dr Allan Jamieson) There was a patch on the left forearm with an anæsthetic centre also a nodule near the right breast The nerves had not undergone any thickening

DR ALEXANDER JAMES showed two cases of Hypokinesis 1 The patient was a girl aged three and a half years The condition affected the right leg arm, and hand which were all smaller in size than were the same members on the left side The loss of power was chiefly in the extensor muscles as shown by the fact that when she grasped anything with the right hand she had to employ the left hand to open the fingers so as to free the object There was loss of power on the right side and the condition had persisted since she was 18 months old. The child suffered from tuberculous abscesses of the bone in the left leg, arm, forehead, &c., when she was seven months old. These healed and then the brain trouble showed itself. The child could not walk, but the right arm had improved under treatment, which had in part consisted in tying up the left hand so as to make her use the right. 2. The patient, a girl, aged 15 years, suffered from epileptic attacks which chiefly affected the right arm but also the face and leg on the same side occasionally. There was also loss of consciousness with some of these attacks. For four or five days at a time peculiar, perfectly regular, tremors persisted. The right arm and leg were weaker and the reflexes were increased. There had evidently been a cortical lesion.

Dr. GEORGE GIBSON showed a man with Pseudo-bulbar Paralysis. He had weakness on both sides of the face and the tongue and difficulty in vocalisation. All the muscles supplied by the seventh cranial and the posterior nerves were greatly weakened, but there was no wasting. He had gradually also developed a spastic condition at first confined to the lower extremities, but now this had invaded the upper extremities. The muscular reactions were increased.

Mr. HAROLD STILES showed: 1. An infant, five months old, after operation for Acute Ileo-cæcal Intussusception. 2. A boy after Mikulicz's Operation for Disease of the Posterior Tarsus. 3. A patient who suffered from Acute Thyroid Cachexia after excision of a suppurating goitre. Both the mother and a sister of the patient had goitres. The patient suffered from great breathlessness and the tumour underwent enlargement very rapidly. The tumour extended behind the sternum and far up in the neck and was difficult to remove on account of the inflammatory adhesions. Two days after the operation the patient developed a strange mental condition. She was "dour" and would not answer questions. Then jaundice supervened and she complained of pains all over her body; the face twitched and she refused food. Immediately after the administration of thyroid extract this apathy disappeared and she was now perfectly well. 4. A man after Excision of a large (simple or malignant?) Lymphoma. The tumour grew very rapidly and the patient's general health deteriorated. The tumour, which was on the right side of the neck, was large and smooth, and the adjoining lymphatic glands were enlarged. The diagnosis was that of tuberculosis or lympho-sarcoma, the latter being more probable. The tumour on section had all the appearances of a medullary tumour. The wound healed rapidly, and some small but hard glands soon disappeared, and three months after removal there was no recurrence of the growth. Microscopically the tumour was that of a lympho-sarcoma. 5. A girl after Avulsion of the whole Scalp. The accident was a machinery one, and the scalp from the forehead to the neck, with part of one ear, was torn away. Two inches of the right parietal bone were bare of pericranium. At first the discharge was great, but now the granulations were less florid and had grown over the bare parietal bone which had not exfoliated. Entire skin grafts had been tried repeatedly and for from two to three weeks had seemed to do well, but these had been eaten up by the granulations. The patient lately while at home had erysipelas but she had now returned for fresh treatment.

Dr. F. D. BOYD exhibited: 1. A man with signs and symptoms of Syringomyelia: diminished visual field; sense of smell almost gone; ocular muscles normal; right trapezius partly paralysed; loss of power in the grasp of both hands; complete paralysis of the right palate and of the abductor of the right vocal cord; some loss of sensation in the palm of the left hand, and atrophy of the thenar and hypothenar eminences and of the interossei. On both sides the deltoid and supra-spinatus muscles were paralysed. 2. A case of Neuritis in a man with Involvement of Both Facial Nerves. After an attack of alcoholic jaundice the patient developed pains all over his body and he was found to be suffering from peripheral neuritis in the legs and arms. In addition he had extreme pain in the angle of the jaw, and over the course of the left facial nerve there was great tenderness with later complete paralysis of the muscles. The right nerve became similarly affected, as did also the motor branch of the fifth nerve. He was now greatly improved. 3. A case of Neuritis after Confinement, to illustrate the question of prognosis. Following on parturition the patient developed a peripheral neuritis with complete ankle- and some wrist-drop. The organic reflexes were abolished and the mental condition was impaired greatly. She had now practically entirely recovered.

Dr. A. C. SYM showed the Trachea, &c., from a case of sudden death due to morbus Ludovici.

Mr. J. M. COTTERILL showed (1) a specimen of a Tumour of the Brain; and (2) two specimens of Urethral Calculi.

Dr. R. B. PURVES showed a specimen of Exostosis of the Femur.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

The Pulmonary Second Sound.—The Examination of Sick Children.

A MEETING of this section was held on Dec. 15th, Dr. J. W. MOORE, the President, being in the chair.

Dr. J. F. O'CARROLL read a paper on the Pulmonary Second Sound and dealt chiefly with the significance of accentuation of the second sound in the pulmonary area.—Sir CHRISTOPHER NIXON, the President, and Dr. J. KNOTT discussed the paper.

Mr. LANGFORD SYMES read a paper on the Examination of Sick Children. The paper dealt with the differences to be observed in children's diseases from those of adults. The organs were taken *seriatim* and in each case its peculiar diseases set forth in the following order: (1) history; (2) "facies"; (3) head; (4) frame and bones; (5) reflexes; (6) eyes, ears, and nose; (7) glands; (8) abdomen; (9) heart; (10) lungs; (11) spine and neck; (12) mouth and throat; and (13) nervous system. In children every organ must be examined, for the discovery of disease could be thus alone secured. Information could not be obtained from the child, the friends were also in ignorance, and so the child was entirely dependent on the physician's powers of physical examination. It was pointed out that mistakes were made almost exclusively from want of examination. No branch of practice of medicine entailed such a pitch of refinement in physical examination, and it formed the best, although severest, school for the clinical investigation of disease.—Mr. DOYLE said that very often in examining sick children it was necessary to resort to an anæsthetic, as he experienced in a recent case under his care of hæmorrhage from the bowel. On making a rectal examination under chloroform he discovered a polypus which was subsequently removed.—Dr. O'CARROLL said that the complaints of children might in many cases be due to the suggestive influence of the parent. Children were also quite as liable to hysteria as adults. He did not consider reflexes of much value in examining children under two or three years of age, as the lateral tract was then ill-developed.—Dr. KNOTT and the PRESIDENT also took part in the discussion.—Mr. SYMES, in reply, alluded to the lack of teaching in diseases of children in Ireland. Now that distinct sections in their associations, separate hospitals, professors and lecturers existed in England, the continent, and America, the subject should no longer be neglected.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Dec. 13th, Dr. Milne Murray, the President, being in the chair.—The President showed a Double Uterus with a Cystic Tumour of the Ovary.—Professor A. R. Simpson showed an Anencephalic Fœtus with some Spina Bifida. It was accompanied by hydramnios, which could not be accounted for by fœtal urination, as the kidneys were small and the bladder showed no signs of having ever been distended.—Professor J. A. C. Kynoch (Dundee) read a paper on Vaginal Cœliotomy. After discussing the history of the operation the technique and different methods were described. In anterior colpotomy the incision might be transverse or longitudinal, the latter being more safe for the ureters. The cellular tissue was then pushed through with the finger in multiparæ and with the aid of scissors in nulliparæ. The peritoneum was exposed and divided; this was accomplished safely by puncturing with long sinus forceps and then separating the blades. The fundus uteri could be brought through the opening and examined, and the appendages could also be inspected and removed if necessary. Drainage, when necessary, was best carried out by the posterior fornix. One of the indications for the operation was in the treatment of retroflexion by vaginal fixation where the symptoms were not relieved by pessary and other treatment. But against its performance was the increasing number of reported cases where operative interference (including Cæsarean section) had been found necessary when labour had occurred in these cases, but it would be suitable for cases at or near the menopause. Inversion of the uterus, if irreducible by other means, might be treated by posterior or anterior colpotomy and the finger then inserted to dilate the constricting ring. A vaginal fixation had been carried out after the reduction. Prolapsed ovaries which were much inflamed and fixed and had resisted other treatment could be easily removed by posterior colpotomy. Extra-uterine pregnancy, which had ruptured, causing diffuse intra-peritoneal hæmorrhage without the formation of a hæmatocele, was universally advised to be treated by abdominal section, but if the condition had been diagnosed before rupture up to the eighth or tenth week the intact tube could be removed by vaginal section. Dührssen gave a table of 19 cases operated on in this way with one death. Ovarian cysts could be removed by vaginal cœliotomy, but the proceeding was not viewed with general favour. Schauta reported 23 cases with one death and limited this method of removal to non-malignant moveable tumours, free from adhesions to the bowel. Colpotomy might be employed in cases of phthisis, cardiac affection, and in other conditions likely to be aggravated by subsequent parturition, to reach the tubes, ligature, and divide them. The advantages claimed for the vaginal route over the abdominal were: (1) shorter convalescence—14 days as compared with from three to four weeks; (2) no abdominal cicatrix, and therefore no tendency to hernia or intestinal or omental adhesions; and (3) less shock on account of the peritoneum being less exposed. Drainage, when necessary, was best carried out through the posterior fornix. Its disadvantages were: (1) on account of the limited space dense adhesions were more difficult to manage and consequently there was greater danger of wounding the bladder and rectum; and (2) there was greater difficulty in rendering the vagina aseptic, but this was probably exaggerated.—Professor Simpson, Dr. N. T. Brewis, Dr. F. W. N. Haultain, and others took part in the discussion.—Dr. Milne Murray read a paper on Pyosalpinx removed by Laparotomy in the Early Puerperium. The patient had been complaining of profuse menses and debility before she became pregnant with her second child. During her pregnancy she had been complaining of a pain in the left ovarian region which occasionally had been very severe, compelling her to lie down for some hours at a time. A child was born with the aid of forceps. The patient's temperature continued about 101° F. till the third day, when it rose to 103.5°. On opening the abdomen and passing the hand down into the left side of the pouch of Douglas many recent adhesions were found which readily gave way. The left tube and ovary were brought out; the tube was intensely congested, much dilated, and to all appearance empty. These were removed; those on the right side were examined and found to be fairly healthy and returned. The recovery was uninterrupted and the uterus underwent normal involution. On examination of the tube pus was found in it at the uterine end. The onset of the symptoms was probably associated with the escape of the purulent contents of the tube into the abdominal cavity.—Dr. G. Simla Paterson read notes on a case of Sudden Death following Labour. The patient was a secundipara, aged 32 years. At the post-mortem examination the heart was found to be affected with both aortic and mitral stenosis. The lungs were markedly congested and portions of both showed microscopically brown induration, chronic congestion, and a recent fibrinous pneumonia. The left kidney was completely cystic and was found to contain a large quantity of tuberculous pus. The right kidney showed signs of chronic nephritis.

SOCIETY OF ANÆSTHETISTS.—At a recent meeting of this society Dr. J. Frederick W. Silk, the President, read a communication from Mr. Walter Edmunds describing a Paper Inhaler for use with Junker's Apparatus for the Administration of Chloroform, the object being to use a new paper in every case.—Mr. W. G. Copestake (Derby) read a paper on a New Inhaler for Ether, Chloroform, or Mixture, the face-piece of which was made of celluloid; he utilised a portion of the angular tube of Clover's inhaler, to which he attached an indiarubber tube by a short brass one. In giving ether he used a flat thin bottle provided with tubes similar to Junker's, the longer one, which reached to the bottom of the bottle, being perforated with a number of small holes. He used Mr. Krohne's indiarubber bellows. The advantages of the inhaler in regard to ether were that in the early part of the administration there was little or no bronchial irritation, there was less struggling or spasm, no cyanosis, much less sickness after recovery, and considerable saving of ether. When chloroform was used the action of the inhaler was the same as that of Junker's; when a mixture of equal parts was used the inhaler combined the action of the two drugs. He had noticed that œdema of the lung occurred much less frequently since he had used the inhaler described.—Dr. G. B. Flux read a paper on a Small Contrivance for use in the Administration of Chloroform. A small metal cylinder was attached at the upper end to the inlet of a ball bellows the delivery tube of which led directly to a face piece. The cylinder contained cotton wick and chloroform was poured on it through the lower open end. The instrument was light, portable, and easily managed and it possessed the advantage that both the strength and the amount of the mixture were absolutely under control.—Mr. Richard Lloyd asked how much longer Mr. Copestake took in putting a patient under ether by his apparatus than by Clover's apparatus. With regard to Dr. Flux's paper Mr. Lloyd wanted to know the definite amount of chloroform taken into the bellows each time.—Mr. Carter Braine asked if any stout and plethoric men had been anæsthetised by Mr. Copestake's method and whether the perforations of the tube got blocked up.—Mrs. Dickinson Berry asked if Mr. Copestake's apparatus could be adapted for the preliminary giving of gas.—Mr. Edgar Willett said that he did not see how the absolute precision could be gained which Dr. Flux claimed for his apparatus.—Dr. Dudley Buxton thought that Mr. Copestake was employing a principle which was absolutely wrong with regard to ether. He did not wish to be ungracious or to attempt to throw cold water on those who brought new apparatus before them, but he was sure that Mr. Copestake and others wanted to hear the candid opinion of the members of the society.—The President said that Mr. Copestake's instrument if used with chloroform seemed to be running against one of the primary axioms of chloroform inhalation in having anything in the nature of a bag attached to a chloroform inhaler. He had found Dr. Flux's apparatus of very great advantage in keeping patients under anæsthesia, but it was rather a difficult matter to work the bellows and to get gross alcoholic patients under.—Mr. Copestake, in replying, said that by his apparatus the time taken was two or three minutes longer than with a Clover, and he could not say that he had had much experience with fat or alcoholic patients. To use his apparatus in conjunction with gas a little tube was merely required to be soldered on to any apparatus which had a face-piece.—Dr. Flux, in reply, said that the air passing through his apparatus would only convey chloroform to the extent of the temperature of the air as it emerged from the chloroform, and that would not be above the temperature of the medium through which the air passed.—Mr. W. J. McCardie read notes of a case of Respiratory and Cardiac Failure during Administration of Chloroform to a patient probably of so-called lymphatic diathesis and Mr. Richard Lloyd narrated the facts of a case which was under his care.—The President, Dr. Dudley Buxton, Mr. Carter Braine, and Mr. Grant Morris took part in the discussion which ensued, and Mr. McCardie and Mr. Richard Lloyd having replied the President concluded the meeting by announcing that on Feb. 2nd the society would discuss the Sequelæ of Ether and other Anæsthetics more especially with regard to pulmonary complaints.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Dec. 22nd at the Guildhall, Windsor, Mr. W. Arnold Thomson (one of the Vice-Presidents) occupying the chair.—21 new members were elected, bringing the membership of the society up to 55.—The discussion on Temperature in Health and Disease, introduced at the November meeting by Dr. M. S. Pembrey, was resumed by Dr. E. D. Hebbert who read notes of an obscure cerebral case which was under the care of Dr. Charlton Bastian some years ago in University College Hospital and in which the temperature on several occasions attained an unusually low level, the minimal rectal temperature being [illegible] F. and the cutaneous temperature at the same time 77.5°. The patient, a man aged 25 years, after a stay of 12 weeks in hospital died comatose, the temperature directly after death rising to [illegible] in the [illegible] had persisted since she was 18 months old. The child suffered from tuberculous abscesses of the bone in the left leg, arm, forehead, &c., when she was seven months old. These healed and then the brain trouble showed itself. The child could not walk, but the right arm had improved under treatment, which had in part consisted in tying up the left hand so as to make her use the right. 2. The patient, a girl, aged 15 years, suffered from epileptic attacks which chiefly affected the right arm but also the face and leg on the same side occasionally. There was also loss of consciousness with some of these attacks. For four or five days at a time peculiar, perfectly regular, tremors persisted. The right arm and leg were weaker and the reflexes were increased. There had evidently been a cortical lesion.

Dr. George Gibson showed a man with Pseudo-bulbar Paralysis. He had weakness on both sides of the face and the tongue and difficulty in vocalisation. All the muscles supplied by the seventh cranial and the posterior nerves were greatly weakened, but there was no wasting. He had gradually also developed a spastic condition at first confined to the lower extremities, but now this had invaded the upper extremities. The muscular reactions were increased.

Mr. Harold Stiles showed: 1. An infant, five months old, after operation for Acute Ileo-cæcal Intussusception. 2. *A boy after Mikulicz's Operation for Disease of the Posterior Tarsus.* 3. A patient who suffered from Acute Thyroid Cachexia after excision of a suppurating goitre. Both the mother and a sister of the patient had goitres. The patient suffered from great breathlessness and the tumour underwent enlargement very rapidly. The tumour extended behind the sternum and far up in the neck and was difficult to remove on account of the inflammatory adhesions. Two days after the operation the patient developed a strange mental condition. She was "down" and would not answer questions. Then jaundice supervened and she complained of pains all over her body; the face twitched and she refused food. Immediately after the administration of thyroid extract this apathy disappeared and she was now perfectly well. 4. A man after Excision of a large (simple or malignant?) Lymphoma. The tumour grew very rapidly and the patient's general health deteriorated. The tumour, which was on the right side of the neck, was large and smooth, and the adjoining lymphatic glands were enlarged. The diagnosis was that of tuberculosis or lympho-sarcoma, the latter being more probable. The tumour on section had all the appearances of a medullary tumour. The wound healed rapidly, and some small but hard glands soon disappeared, and three months after removal there was no recurrence of the growth. Microscopically the tumour was that of a lympho-sarcoma. 5. A girl after Avulsion of the whole Scalp. The accident was a machinery one, and the scalp from the forehead to the neck, with part of one ear, was torn away. Two inches of the right parietal bone were bare of pericranium. At first the discharge was great, but now the granulations were less florid and had grown over the bare parietal bone which had not exfoliated. Entire skin grafts had been tried repeatedly and for from two to three weeks had seemed to do well, but these had been eaten up by the granulations. The patient lately while at home had erysipelas but she had now returned for fresh treatment.

Dr. F. D. Boyd exhibited: 1. A man with signs and symptoms of Syringomyelia: diminished visual field; sense of smell almost gone; ocular muscles normal; right trapezius partly paralysed; loss of power in the grasp of both hands; complete paralysis of the right palate and of the abductor of the right vocal cord; some loss of sensation in the palm of the left hand, and atrophy of the thenar and hypothenar eminences and of the interossei. On both sides the deltoid and supra-spinatus muscles were paralysed. 2 A case of Neuritis in a man with Involvement of Both Facial Nerves. After an attack of alcoholic jaundice the patient developed pains all over his body and he was found to be suffering from peripheral neuritis in the legs and arms. In addition he had extreme pain in the angle of the jaw, and over the course of the left facial nerve there was great tenderness with later complete paralysis of the muscles. The right nerve became similarly affected, as did also the motor branch of the fifth nerve He was now greatly improved. 3 A case of Neuritis after Confinement, to illustrate the question of prognosis. Following on parturition the patient developed a peripheral neuritis with complete ankle- and some wrist-drop. The organic reflexes were abolished and the mental condition was impaired greatly. She had now practically entirely recovered.

Dr. A. O. Sym showed the Trachea, &c., from a case of sudden death due to morbus Ludovici.

Mr. J. M. Cotterill showed (1) a specimen of a Tumour of the Brain; and (2) two specimens of Urethral Calculi.

Dr. R. B. Purves showed a specimen of Exostosis of the Femur.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

The Pulmonary Second Sound.—The Examination of Sick Children.

A meeting of this section was held on Dec. 15th, Dr. J. W. Moore, the President, being in the chair.

Dr. J. F. O'Carroll read a paper on the Pulmonary Second Sound and dealt chiefly with the significance of accentuation of the second sound in the pulmonary area.—Sir Christopher Nixon, the President, and Dr. J. Knott discussed the paper.

Mr. Langford Symes read a paper on the Examination of Sick Children. The paper dealt with the differences to be observed in children's diseases from those of adults. The organs were taken *seriatim* and in each case its peculiar diseases set forth in the following order: (1) history; (2) "facies"; (3) head; (4) frame and bones; (5) reflexes; (6) eyes, ears, and nose; (7) glands; (8) abdomen; (9) heart; (10) lungs; (11) *spine and neck*; (12) *mouth and* throat; and (13) nervous system. In children every organ must be examined, for the discovery of disease could be thus alone secured. Information could not be obtained from the child, the friends were also in ignorance, and so the child was entirely dependent on the physician's powers of physical examination. It was pointed out that mistakes were made almost exclusively from want of examination. No branch of practice of medicine entailed such a pitch of refinement in physical examination, and it formed the best, although severest, school for the clinical investigation of disease —Mr. Doyle said that very often in examining sick children it was necessary to resort to an anæsthetic, as he experienced in a recent case under his care of hæmorrhage from the bowel. On making a rectal examination under chloroform he discovered a polypus which was subsequently removed.—Dr. O'Carroll said that the complaints of children might in many cases be due to the suggestive influence of the parent. Children were also quite as liable to hysteria as adults. He did not consider reflexes of much value in examining children under two or three years of age, as the lateral tract was then ill-developed.—Dr. Knott and the President also took part in the discussion —Mr. Symes, in reply, alluded to the lack of teaching in diseases of children in Ireland. Now that distinct sections in their associations, separate hospitals, professors and lecturers existed in England, the continent, and America, the subject should no longer be neglected.

Edinburgh Obstetrical Society.—A meeting of this society was held on Dec. 13th, Dr. Milne Murray, the President, being in the chair.—The President showed a Double Uterus with a Cystic Tumour of the Ovary.—Professor A. R. Simpson showed an Anencephalic Fœtus with some Spina Bifida. It was accompanied by hydramnios, which could not be accounted for by fœtal urination, as the kidneys were small and the bladder showed no signs of having ever been distended.—Professor J. A. C. Kynoch (Dundee) read a paper on Vaginal Cœliotomy. After discussing the history of the operation the technique and different methods were described. In anterior colpotomy the incision might be transverse or longitudinal, the latter being more safe for the ureters. The cellular tissue was then pushed through with the finger in multiparæ and with the aid of scissors in nulliparæ. The peritoneum was exposed and divided; this was accomplished safely by puncturing with long sinus forceps and then separating the blades. The fundus uteri could be brought through the opening and examined, and the appendages could also be inspected and removed if necessary. Drainage, when necessary, was best carried out by the posterior fornix. One of the indications for the operation was in the treatment of retro flexion by vaginal fixation where the symptoms were not relieved by pessary and other treatment. But against its performance was the increasing number of recorded cases where operative interference [illegible] (Cæsarean section) had been [illegible] necessary [illegible] in these cases, [illegible]

[illegible]

A large chart of the temperature was shown and a number of authorities on the subject of hypothermia were quoted.—Mr. W. F. Lloyd said that he did not consider that in fracture of the cervical spine the rise of temperature was due to the hot water bottles with which the patient might be surrounded. He had devoted much attention to the subject of the specific heat of the human body and he calculated that the amount of boiling water required to cause the temperature of a patient weighing 10 stones to rise 7° F. would be seven and a half pints and that amount would have to be poured into the patient's body, so that none of the heat should be lost. In many cases requiring operation he thought the subsequent fall of temperature was due rather to the evacuation of pus than to the anæsthetic.—Deputy-Surgeon-General H. Cayley referred to the post-mortem rise of temperature in cases of cholera, often amounting to 6° or 7° in a few hours, and said that under these circumstances the pathologist's hands experienced the sensation even of being "burned."—Mr. R. Shalders Miller said that he had seen a case of ascending neuritis of gouty origin in which the temperature marked 109°, and had successfully treated by cold effusions a patient who, whilst suffering from puerperal eclampsia, developed a temperature of 108°.—Mr. E. Weaver-Adams quoted the case of a patient, formerly under the care of Dr. D. Ferrier, who developed a temperature of 110° without obvious cause, all precautions having been taken to ensure a genuine record. He also quoted the case of a man suffering from syringomyelia who, directly after an operation for hernia, presented a reading of 105°, there being nothing in the condition of the wound to account for it.—Dr. A. J. Anderson, Mr. H. E. Bruce Porter, and others also took part in the discussion.—Dr. G. Leslie Eastes, Director of the Clinical Research Laboratories, London-bridge, S.E., next gave a Bacteriological Demonstration very practical in character and illustrated by apparatus and microscopical preparations. After a demonstration of Widal's test he passed on to puerperal fever, the varieties of "septicæmia" (so-called) being distinguished. The diagnosis of septicæmia in difficult cases could be made by an examination of the blood, and he advocated the "cultural" rather than the "direct" method. A swabbing from the uterus was also sometimes useful and the correct method of obtaining this was described. If streptococci be found both in the blood and in the swabbing there was certainly justification for using the serum. If the blood was sterile but streptococci were found in the swab its use was still justified, because the result under such circumstances was still inconclusive, and because the serum would act as a prophylactic. He then treated of streptococcal infection in other parts of the body and called attention to the fact that streptococci were normal inhabitants of the mouth, the large intestine, and the vulva. Occasionally the streptococcus was the cause of certain cases of food-poisoning. He had himself found them in 80 per cent. of some 200 samples of mixed milk which he had examined. From culture observations which he had made Dr. Eastes believed that this micro-organism was identical with that of bovine mastitis, that it would be proved to be pathogenic for man, and if so that the use of such milk unboiled was the probable cause of a certain proportion of the cases of autumnal diarrhœa in infants.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 14th, the President, Dr. Macnaughton Jones, being in the chair.—Dr. E. Doyen of Paris, who had come over expressly for the purpose, gave an admirable demonstration of Gynæcological Operations by means of the Kinematograph. He first referred to the progress of surgery during the present century as being the result of the introduction of anæsthesia and antisepsis, and then described how he had set himself, when he first practised surgery, to the task of simplifying technique and of shortening the duration of major operations. He sought to apply to abdominal surgery the established principles of the operative surgery of the extremities as practised by the pre-antiseptic surgeons. He was glad to think that his efforts had been crowned with success. He passed on to consider the value of the kinematograph as a teaching instrument, pointing out that the teaching of operative surgery for such operations as could not be demonstrated on the dead body had always been much inferior to the teaching of clinical surgery and of surgical pathology. Too few students could follow with profit the details of such operations in the operating theatre. The kinematograph would fill this blank and complete the surgical training given to students in the future. Dr. Doyen then proceeded with his demonstration as follows:—(1) 14 slides showing the steps in an ovariotomy and the details in the use of Doyen's lever clamp-forceps; (2) a complete kinematographic representation of an ovariotomy; (3) 24 slides illustrative of Dr. Doyen's method of abdominal hysterectomy; (4) kinematographic reproductions of three abdominal hysterectomies; (5) 38 fixed slides illustrating the technique in vaginal hysterectomy; and (6) four vaginal hysterectomies as recorded by the kinematograph, showing the possibility of demonstrating to hundreds what half a dozen could not see so well in an operating theatre. After the gynæcology demonstration Dr. Doyen showed, by special request, a kinematograph of a nephrectomy and of a thyroidectomy.—Dr. C. H. F. Routh moved a hearty vote of thanks to Dr. Doyen for his most excellent, interesting, and instructive demonstration and for his kindness in coming over from Paris expressly to give it.—This was seconded by Mr. W. D. Spanton of Hanley, supported by Dr. Clement Godson, and carried with enthusiasm.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 21st, Dr. Macfie Campbell, the President, being in the chair.—The following resolution, proposed by Mr. T. M. Dawson and seconded by Dr. J. J. O'Hagan, was carried:—

> Owing to the fact that the present war in South Africa has necessitated the calling out of our Reservists and Volunteers for active service, many of whom have left behind them wives and families in straitened circumstances, we, the members of the Medical Institution, are willing to give our professional services gratuitously to the said wives and families provided that the cases are authenticated by some recognised authority and that our services do not interfere with the relations of such families and their present medical attendant.

—Dr. William Carter read a note on Digestives, demonstrating the inutility of many vaunted preparations and counselling adhesion to the British Pharmacopœia preparations of pepsin.—Mr. Laird Pearson, Dr. J. C. M. Given and Dr. J. J. O'Hagan spoke.—Dr. T. B. Grimsdale related a case of Fibroid Tumour of the Uterus which produced Ascites. The patient was a woman aged 67 years. The tumour had existed for years and the menopause occurred at fifty years. For twelve months the abdomen had increased in size and she had difficulty in getting about. The skin of the abdomen was tense and shiny and the girth measurement was 40 inches. The abdomen was opened, liberating two gallons of ascitic fluid, and a hard solid tumour was removed from the uterus, its attachment to the uterus was severed, and the stump was sutured by a continuous suture. The patient made a good recovery.—Dr. J. E. Gemmell and Dr. J. J. O'Hagan spoke.—Dr. Charles MacAlister read notes of two cases of Chronic Parenchymatous Nephritis, illustrating the good results following prolonged treatment.—Dr. William Carter bore testimony to the Utility of Mercury and Morphia in some cases of Bright's Disease.—Dr. G. G. Gullan and Dr. F. H. Barendt spoke.—Dr. John E. Gemmell read a paper on Ectopic Pregnancy.—Dr. R. J. M. Buchanan observed that in the microscopic examination of doubtful specimens he had found nucleated red blood corpuscles when he had failed to find chorionic villi, and suggested that their presence was of considerable importance and they should always be looked for.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Dec. 19th, Dr Judson S. Bury, the President, being in the chair.—Mr. Thomas Jones made some remarks on Fixation of Flail-like Joints (Arthrodesis) and showed cases.—Mr. E. Stanmore Bishop reported the case of a married woman, aged 26 years, who had one child five years of age and had had one miscarriage three and a half years before, from whom, in 1897, he removed an ordinary ovarian cyst springing from the right side. Recovery was complete and the patient remained in perfect health until July, 1899, when she was attacked by severe pain in the left iliac region. The menstrual flow came on at this date and was normal in time but excessive in quantity and associated with much more pain than usual. From this date she believed herself to be pregnant, having morning sickness, enlarged breasts, &c. The periods recurred twice, each time greatly accentuating the pain, which was continuous in the left side and passing down the thigh. The last menstrual flow was shreddy and the pain was described as "labour pains." Vagino-bimanual examination revealed a small,

A large chart of the temperature was shown and a number of authorities on the subject of hypothermia were quoted.—Mr. W. F. Lloyd said that he did not consider that in fracture of the cervical spine the rise of temperature was due to the hot water bottles with which the patient might be surrounded. He had devoted much attention to the subject of the specific heat of the human body and he calculated that the amount of boiling water required to cause the temperature of a patient weighing 10 stones to rise 7° F. would be seven and a half pints and that amount would have to be poured into the patient's body, so that none of the heat should be lost. In many cases requiring operation he thought the subsequent fall of temperature was due rather to the evacuation of pus than to the anæsthetic.—Deputy-Surgeon-General H. Cayley referred to the post-mortem rise of temperature in cases of cholera, often amounting to 6° or 7° in a few hours, and said that under these circumstances the pathologist's hands experienced the sensation even of being "burned."—Mr. R. Shalders Miller said that he had seen a case of ascending neuritis of gouty origin in which the temperature marked 109°, and had successfully treated by cold effusions a patient who, whilst suffering from puerperal eclampsia, developed a temperature of 108°.—Mr. E. Weaver-Adams quoted the case of a patient, formerly under the care of Dr. D. Ferrier, who developed a temperature of 110° without obvious cause, all precautions having been taken to ensure a genuine record. He also quoted the case of a man suffering from syringomyelia who, directly after an operation for hernia, presented a reading of 105°, there being nothing in the condition of the wound to account for it.—Dr. A. J. Anderson, Mr. H. E. Bruce Porter, and others also took part in the discussion.—Dr. G. Leslie Eastes, Director of the Clinical Research Laboratories, London-bridge, S.E., next gave a Bacteriological Demonstration very practical in character and illustrated by apparatus and microscopical preparations. After a demonstration of Widal's test he passed on to puerperal fever, the varieties of "septicæmia" (so-called) being distinguished. The diagnosis of septicæmia in difficult cases could be made by an examination of the blood, and he advocated the "cultural" rather than the "direct" method. A swabbing from the uterus was also sometimes useful and the correct method of obtaining this was described. If streptococci be found both in the blood and in the swabbing there was certainly justification for using the serum. If the blood was sterile but streptococci were found in the swab its use was still justified, because the result under such circumstances was still inconclusive, and because the serum would act as a prophylactic. He then treated of streptococcal infection in other parts of the body and called attention to the fact that streptococci were normal inhabitants of the mouth, the large intestine, and the vulva. Occasionally the streptococcus was the cause of certain cases of food-poisoning. He had himself found them in 80 per cent. of some 200 samples of mixed milk which he had examined. From culture observations which he had made Dr. Eastes believed that this micro-organism was identical with that of bovine mastitis, that it would be proved to be pathogenic for man, and if so that the use of such milk unboiled was the probable cause of a certain proportion of the cases of autumnal diarrhœa in infants.

British Gynæcological Society.—A meeting of this society was held on Dec. 14th, the President, Dr. Macnaughton-Jones, being in the chair.—Dr. E. Doyen of Paris, who had come over expressly for the purpose, gave an admirable demonstration of Gynæcological Operations by means of the Kinematograph. He first referred to the progress of surgery during the present century as being the result of the introduction of anæsthesia and antisepsis, and then described how he had set himself, when he first practised surgery, to the task of simplifying technique and of shortening the duration of major operations. He sought to apply to abdominal surgery the established principles of the operative surgery of the extremities as practised by the pre-antiseptic surgeons. He was glad to think that his efforts had been crowned with success. He passed on to consider the value of the kinematograph as a teaching instrument, pointing out that the teaching of operative surgery for such operations as could not be demonstrated on the dead body had always been much inferior to the teaching of clinical surgery and of surgical pathology. Too few students could follow with profit the details of such operations in the operating theatre. The kinematograph would fill this blank and complete the surgical training given to students in the future. Dr. Doyen then proceeded with his demonstration as follows:—(1) 14 slides showing the steps in an ovariotomy and the details in the use of Doyen's lever clamp-forceps; (2) a complete kinematographic representation of an ovariotomy; (3) 24 slides illustrative of Dr. Doyen's method of abdominal hysterectomy; (4) kinematographic reproductions of three abdominal hysterectomies; (5) 38 fixed slides illustrating the technique in vaginal hysterectomy; and (6) four vaginal hysterectomies as recorded by the kinematograph, showing the possibility of demonstrating to hundreds what half a dozen could not see so well in an operating theatre. After the gynæcology demonstration Dr. Doyen showed, by special request, a kinematograph of a nephrectomy and of a thyroidectomy.—Dr. C. H. F. Routh moved a hearty vote of thanks to Dr. Doyen for his most excellent, interesting, and instructive demonstration and for his kindness in coming over from Paris expressly to give it.—This was seconded by Mr. W. D. Spanton of Hanley, supported by Dr. Clement Godson, and carried with enthusiasm.

Liverpool Medical Institution.—A meeting of this society was held on Dec. 21st, Dr. Macfie Campbell, the President, being in the chair.—The following resolution, proposed by Mr. T. M. Dawson and seconded by Dr. J. J. O'Hagan, was carried:—

> Owing to the fact that the present war in South Africa has necessitated the calling out of our Reservists and Volunteers for active service, many of whom have left behind them wives and families in straitened circumstances, we, the members of the Medical Institution, are willing to give our professional services gratuitously to the said wives and families provided that the cases are authenticated by some recognised authority and that our services do not interfere with the relations of such families and their present medical attendant.

—Dr. William Carter read a note on Digestives, demonstrating the inutility of many vaunted preparations and counselling adhesion to the British Pharmacopœia preparations of pepsin.—Mr. Laird Pearson, Dr. J. C. M. Given and Dr. J. J. O'Hagan spoke.—Dr. T. B. Grimsdale related a case of Fibroid Tumour of the Uterus which produced Ascites. The patient was a woman aged 67 years. The tumour had existed for years and the menopause occurred at fifty years. For twelve months the abdomen had increased in size and she had difficulty in getting about. The skin of the abdomen was tense and shiny and the girth measurement was 40 inches. The abdomen was opened, liberating two gallons of ascitic fluid, and a hard solid tumour was removed from the uterus, its attachment to the uterus was severed, and the stump was sutured by a continuous suture. The patient made a good recovery.—Dr. J. E. Gemmell and Dr. J. J. O'Hagan spoke.—Dr. Charles MacAlister read notes of two cases of Chronic Parenchymatous Nephritis, illustrating the good results following prolonged treatment.—Dr. William Carter bore testimony to the Utility of Mercury and Morphia in some cases of Bright's Disease.—Dr. G. G. Gullan and Dr. F. H. Barendt spoke.—Dr. John E. Gemmell read a paper on Ectopic Pregnancy.—Dr. R. J. M. Buchanan observed that in the microscopic examination of doubtful specimens he had found nucleated red blood corpuscles when he had failed to find chorionic villi, and suggested that their presence was of considerable importance and they should always be looked for.

Clinical Society of Manchester.—A meeting of this society was held on Dec. 19th, Dr Judson S. Bury, the President, being in the chair.—Mr. Thomas Jones made some remarks on Fixation of Flail-like Joints (Arthrodesis) and showed cases.—Mr. E. Stanmore Bishop reported the case of a married woman, aged 26 years, who had one child five years of age and had had one miscarriage three and a half years before, from whom, in 1897, he removed an ordinary ovarian cyst springing from the right side. Recovery was complete and the patient remained in perfect health until July, 1899, when she was attacked by severe pain in the left iliac region. The menstrual flow came on at this date and was normal in time but excessive in quantity and associated with much more pain than usual. From this date she believed herself to be pregnant, having morning sickness, enlarged breasts, &c. The periods recurred twice, each time greatly accentuating the pain, which was continuous in the left side and passing down the thigh. The last menstrual flow was shreddy and the pain was described as "labour pains." Vagino-bimanual examination revealed a small, painful, elastic mass by the side of a normal uterus and not continuous with it *Abdominal section was performed and* the mass was removed The patient made a good recovery On and after removal the mass closely resembled an unruptured ectopic pregnancy but was found to consist of a small ovarian cyst surrounded by the dilated tubal ampulla which had become firmly adherent to it Mr Bishop described the case as illustrating the difficulty of abdominal diagnosis even after laparotomy The specimen was shown —Dr A T Wilkinson read a paper on Acute Pleural Effusion, with special reference to diagnosis and treatment

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY —A meeting of this society was held at Owens College Manchester, on Dec 15th the President Dr A Donald, being in the chair —Dr J E Gemmell of Liverpool showed a Fœtus and Placental Sac from a case of Abdominal Pregnancy The mass was removed by abdominal section the patient making a good recovery Microscopic sections of the Fallopian tube were shown The rupture had occurred close to the uterine end of the tube and the placenta had developed mainly in the expanded and everted Fallopian tube —Dr J B Hellier showed 1 A Uterus with Multiple Fibroids and Double Pyosalpinx Removed by Panhysterectomy, carried out by the "*combined method*' The patient *made a* good recovery 2 A case of Vesicular Disease of the Great Omentum —Dr D Lloyd Roberts showed a Cystic Tumour of the Kidney of the size of an adult head The tumour was successfully removed by abdominal section —The President then gave a Presidential Address entitled Minor Gynæcology In reviewing the changes which had occurred in the practice of minor gynæcology during the last 15 years he dwelt especially on the following four points (1) the use of pessaries, (2) the use of the uterine sound for diagnosis and treatment, (3) caustics and other irritants in the treatment of cervical catarrh, and (4) the methods adopted in out patient practice for the management of minor gynæcological ailments *He thought that there was considerable divergence* in our practice from that which prevailed widely in the early "eighties"

Reviews and Notices of Books.

Encyclopædia Medica *Under the General Editorship of* CHALMERS WATSON, M B, M R C P Edin Vol II Brachial Plexus to Digestion Edinburgh William Green and Sons 1899 Pp 562

IN our review of the *first volume of this publication* we commented on its *general scope* The articles in the *present* volume are, as a whole, better than those which appeared in its predecessor and doubtless as a work of reference it will be found valuable by the general practitioner The contributions on Brain are particularly good and are five in number, each written by a different author Dr A Bruce writes an able paper on the Physiology of the Brain, and the complex structure and the functions, so far as are at present known are well described, Dr James Taylor contributes a praiseworthy article on Affections of Blood-vessels of the Brain Some of the articles in the first volume had apparently been needlessly curtailed, but Dr Taylor considers at length the pathological lesions connected with anæmia, hyperæmia, and œdema of the brain, cerebral hæmorrhage thrombosis and embolism, and details the conditions which may result from the vascular lesions Dr Risien Russell's original researches amply qualify him to write on Cerebral Tumours and later in the book he also has an article on the Cerebellum, and in both he shows a knowledge of his subject which makes his contributions specially valuable Dr R A Fleming writes on Atrophy, Hypertrophy, Inflammations, and Cysts of the Brain, and Mr J M Cotterill on Intracranial Surgery, the latter article being particularly interesting

Dr Arthur Voelcker's contribution on Bronchial Glands contains much that is interesting and Dr Watson Williams's paper on Bronchitis although containing nothing that is new, is a good summary of our present knowledge on the subject *The subject of Bronchiectasis* is dealt with by Dr S H Habershon He speaks favourably of the treatment by the continuous inhalation of creasote It is probably more successful than any other method in severe cases but has the disadvantage of requiring a room to be set apart for the purpose The subject of Cataract has been left in the hands of Mr G A Berry and the author *has accomplished his task very ably* The question and modes of operation are fully discussed and special attention is paid to the after treatment of cataract extraction

A useful paper on the Development and Clinical Examination of Children is contributed by Dr John Thomson It shows the results of experience and close observation and contains many useful hints that practitioners will do well to take advantage of

Dr Andrew Davidson's article on Asiatic Cholera will *probably receive some attention, especially his remarks on* Prophylaxis

We would also commend to the notice of our readers Mr H E Juler's paper on Diseases of the Choroid The main part of it is naturally devoted to a description of the various forms of choroiditis, but observations are also made on the manner in which tubercle may attack the choroid and also on sarcoma of the choroid

A good account of Diseases of the Colon is given by Dr W Hale White In describing membranous *colitis* two varieties are noticed, one which he terms ' dyspeptic membranous colitis *because the sufferers from it complain much* of dyspepsia while exhibiting the characteristic symptom of passing membrane by the bowel, and the other ' secondary membranous colitis , this latter form is always associated with some other grave condition or is due to direct injury For the treatment of severe membranous colitis in which all means of relief by ordinary methods have been tried in vain, Dr White advises that the colon should be opened on the right side, so as to give the diseased bowel complete rest, after some time the artificial anus may be closed The published cases in which this course has been *followed are on the whole encouraging*

Another interesting article is that by Mr T H Bickerton *on Colour Vision* The ' *physiological considerations'* are expressed clearly and at length and preference is given to the theory first expounded by Young and Helmholtz, based on the assumption of the existence of three kinds of nerve-fibres identical as to structure and construction but terminating in different end organs endowed with photo chemical substances respectively sensitive to the three primary colours—red, green and blue

Mr. A H. Tubby writes on Deformities, and he has managed to compress a large amount of information into a comparatively small space

Amongst other contributions we may mention the following —Dermatitis Herpetiformis, by Dr J J Pringle, *Dermatitis Repens by Dr Radcliffe Crocker, an excellent* article on Diabetes Mellitus by Dr R T Williamson, and Cretinism by *Dr John Thomson*

Laboratory Work in Bacteriology By FREDERICK G NOVY, Sc D M D, Junior Professor of Hygiene and Physiological Chemistry, University of Michigan Second Edition Ann Arbor Geo Wahr 1899 Pp 563 Price $3 00

IN the University of Michigan all students of medicine have to attend a practical course of bacteriology which occupies every afternoon for a period of 12 weeks It is not unlikely that a time may come when as thorough a course will form a necessary part of the student's curriculum in this country If it does so the scheme of laboratory work set forth in this volume by Professor Novy will be found as useful, comprehensive, and thorough as could be wished. It differs in many respects from most of the similar works with which we are acquainted. It is not purely a laboratory course of instruction. The first five chapters are devoted to general bacteriology and contain such an account of the morphology, classification, life-history, and chemistry of bacteria as to render intelligible to the student the remaining part of the book. These chapters occupy some 120 pages; they are well written, accurate, and clear, and they contain all the information which the ordinary student requires. A full optical account of the microscope is by no means out of place as a preface to the examination of living bacteria. Everyone who has had any experience in teaching bacteriology knows what marvellous misuse is often made of an oil immersion lens by the beginner. The preparation of gelatin and potato media is next described, together with the methods of cultivating bacteria thereon. The student is then introduced to some 20 characteristic non-pathogenic organisms *seriatim*; a concise account of each is given and the opposite page is left blank for notes and drawings. The preparation of bouillon, agar-agar, milk, and other culture media follows next in order, with a description of incubators and other accessories. The relation of bacteria to disease is then shortly discussed, together with methods of inoculation and of post-mortem examination of infected animals; to this is added a full account of laboratory work with animals dead from anthrax. Pathogenic bacteria are described in a curious order, the anaerobes taking precedence of the aerobes. The methods of anaerobic cultivation are given and in this place the staining of flagella is described, Löffler's method being alone given, though in our opinion better ones have since been introduced. 31 pathogenic bacteria are described in detail—most of them on a single page, with a blank page opposite, as in the case of the non-pathogenic forms. But to some of the more important species, such as the tubercle bacillus, more space is allotted. 14 species of yeasts, moulds, and streptothrices are similarly described. The last three chapters deal with the bacteriological examination of water, soil, and air, and with a number of special methods of work, such as the preparation of toxins and antitoxins, the agglutination of bacteria by serum, the testing of disinfectants, and other advanced subjects.

We have described the method and scope of Professor Novy's book in some detail because in all respects it appears to us to embody a most logically devised scheme of instruction in bacteriology, and one that may well be taken as a model in framing an extended course in the subject for students. The work is well printed and the diagrams of apparatus are clear and good. No illustrations of the different species of organisms are given because the student is expected to learn their appearances from actual specimens and with this no fault can be found. We can most heartily recommend the book to all teachers of bacteriology.

Handbuch der Gynäkologie. (*Handbook of Gynæcology*) Edited by Professor VEIT. Third Volume, Second Half, Second Part. With 65 Illustrations in the Text and Three Plates. Wiesbaden: T. F. Bergmann. 8vo. Pp. 466. 1899. Price 18 marks.

THIS part forms the concluding volume of Professor Veit's Handbook of Gynæcology. The subjects considered include Pelvic Hæmatocele, Diseases of the Tubes, General Peritonitis, and Sarcoma of the Uterus. The article upon Pelvic Hæmatocele is written by Professor Winternitz. In accordance with recent views extra-uterine gestation is considered as the commonest cause of this condition. Numerous other causes are, however, enumerated, and such evidence as exists is quoted in favour of the possibility of an intraperitoneal collection of blood being due to menstruation, diseases of the tubes, varicose veins of the broad ligaments, and new growths. Sänger's division of hæmatoceles into solitary and diffuse is adopted. The symptoms, general and local, are well and fully described, and the frequency of a tubal abortion or tubal mole as the cause rather than a rupture of the gravid tube is pointed out. The length of time required for absorption of the blood renders it impossible to recommend expectant treatment except in cases where the necessary rest in bed can be obtained, and for this reason expectant treatment amongst the poor and those who have to earn their living is seldom admissible. The author recommends laparotomy in the majority of instances and condemns exploratory puncture. In only a small minority of cases is posterior colpotomy an advisable operation—for instance, where a large hæmatocele is present not due to a tubal abortion, where the patient's general condition contraindicates laparotomy, or where the hæmatocele is suppurating.

Diseases of the Tubes are described by the editor and Dr. Kleinhans. The latter is responsible for the section upon the etiology and pathological anatomy. A very complete account is given of the congenital and acquired deformities and anomalies of the tubes. The section on the pathological anatomy is illustrated by a number of good drawings, taken chiefly from the author's own preparations. The distinctions between the two main varieties of pyosalpinx, the gonorrhœal and puerperal, are clearly differentiated. The view that a hydrosalpinx can be the ultimate stage of a pyosalpinx is regarded as not proved. Tuberculous disease of the tubes is fully considered and the author thinks that an important part is played by gonorrhœa in both its acute and chronic stages in preparing the way for the tubercle bacillus. Previous inflammatory conditions are also held to be of etiological importance in cases of carcinoma of the tubes.

Professor Veit discusses the Symptoms, Diagnosis, Prognosis, and Treatment of Diseases of the Tubes. The complex group of symptoms met with in the various stages of tubal diseases are clearly presented and a striking clinical picture is drawn of the varying conditions of the patient. A timely warning is given against the too frequent employment of exploratory laparotomy, and stress is laid upon the examination of doubtful cases by means of a posterior colpotomy.

The relative value of the vaginal and abdominal routes in operating is very fully gone into, the author coming to the only possible conclusion—viz., that all cases cannot be treated in any hard and fast manner but each case must be considered separately. Under certain circumstances vaginal operations are no doubt the best, but any attempt to deal with every case in such a way would be very likely to lead to disaster.

In considering general peritonitis Professor Döderlein distinguishes an infectious variety, including septic, putrid, gonorrhœal, and tuberculous, and a non-infectious, including mechanical and chemico toxic. In cases of puerperal septic peritonitis the organisms most commonly found are the streptococcus, staphylococcus, pneumococcus, and the colon bacillus. Operative treatment in cases of perforative peritonitis must be carried out very early if it is to do any good. Septic peritonitis due to the streptococcus is almost uniformly fatal.

The two articles upon Sarcoma and Endothelioma of the Uterus are from the pen of Professor Gessner. He calculates that sarcoma of the uterus occurs in the proportion of about one case to every 40 cases of carcinoma When the disease starts in the mucous membrane of the body of the uterus the periods of life at which it most commonly occurs are puberty and the years just before and after the menopause. Sarcoma of the wall of the uterus occurs at the same time but rather less frequently at the age of puberty. A very full and careful account is given of the pathological anatomy of the three main varieties of sarcoma of the uterus—viz., sarcoma of the mucous membrane, of the wall of the uterus, and of the cervix. All the recorded cases of the latter kind are collected in a table. The importance of the microscope in the diagnosis of sarcomatous changes in the mucous membrane is indicated and a number of clinical rules are laid down as a guide to the recognition of sarcomatous changes in a myoma of the uterus.

Professor Gessner gives a full analysis of the six cases of Endothelioma of the Uterus which have been recorded up to the present time. The vexed question of the relation of these growths to carcinomata or sarcomata he is content to leave for the present undecided.

Subject and name indices complete the volume. The paper and printing are good and the illustrations are well reproduced. A very complete bibliography precedes each article. The editor and his collaborators are to be congratulated upon the success of their labours. A high standard of excellence has been maintained throughout the work. The book is one of the best of its kind and furnishes a very complete account of the present views of German gynæcologists.

Text-book of the Embryology of Invertebrates. By Dr. E. KORSCHELT and Dr. K. HEIDER. Translated from the German by MATILDA BERNARD. Revised and edited, with additional notes, by MARTIN F. WOODWARD. London: Swan Sonnenschein and Co., Limited. 1899. Vol. ii., pp. xv., 375; Vol. iii., pp. xii., 441. Price: Vol. ii., 12*s.*; Vol. iii., 14*s.*

THE translation and publication of Volumes II. and III. of this excellent German work are at last *un fait accompli* and their appearance will give much satisfaction to zoologists, both teachers and students. Volume II. treats of the Phoronidea, Bryozoa, Ectoprocta, Brachiopoda, Entoprocta, Crustacea, and the Palæostraca; while, on the other hand, Volume III. enters into the consideration of the development of the Arachnida, Pentastomidæ, Pantopoda, Tardigrada, Onychophora, Myriopoda, and finally the Insecta, which group is somewhat more fully considered than the others contained in this volume.

Investigation at the present time is so active that there is a possibility of a translated work becoming slightly out of date, this being due, of course, to the time absorbed by the rendering and the delays which are unavoidable in the publication; this is more especially the case when the work concerned is of some size. In the work under consideration, however, this danger has been guarded against; the more important results which have been obtained from recent investigation having been added in the convenient form of footnotes, so that the work is up-to-date as far as possible. The value of this work is enhanced by the addition of lists of literature at the end of each chapter, which lists, in some cases, are of quite a considerable length; for instance, in the literature dealing with the Insecta more than 210 references are given. Here again the work has been kept up-to-date as far as possible by the addition of references to the more important recent literature under the form of appendices at the end of each chapter. The translation has been extremely well done; we could wish that all translated scientific works were so eminently readable.

The get-up of these two volumes leaves very little indeed, if anything, to be desired; the type is clear, the paper is good, and the books are of a convenient size. The text is fully illustrated, there being over 360 figures, which on the whole are extremely clear, in the two volumes.

Although there may be a certain amount of matter which is beyond the depth of the more general biologist, still without doubt he will be able to find much to occupy his attention. To pick out a few examples of more general interest, the survey of the Arachnidan eyes and the metamorphosis of insects may be mentioned. Then, again, there is a very interesting account of Parthenogenesis, while those interested in problems of a bionomical character will find a brief account of the migration of different generations of the Aphidæ and Chermetidæ from one plant to another. For example, in the case of the former "a winged parthenogenetic generation frequently appears and then may migrate to a different plant, there to reproduce itself, and in a later generation returns to the original host."

After what has been said it is hardly necessary to add that we can highly recommend this work to all who are interested in this branch of zoology.

Atlas und Grundriss der Bakteriologie, und Lehrbuch der Speziellen Bakteriologischen Diagnostik. Von Professor K. B. LEHMANN und Dr. R. O. NEUMANN. Zweite vermehrte und verbesserte Auflage. (*Atlas and Essentials of Bacteriology, and Manual of Special Bacteriological Diagnosis.* By Professor K. B. LEHMANN and Dr. R. O. NEUMANN. Second enlarged and improved edition.) Munich: J. F. Lehmann. 1899. Pp. xv., 495. Plates, 69. Price 16 marks.

THE first German edition of this useful work appeared rather more than three years ago. In November, 1897, we had occasion to review an abridged English translation in one volume. We then expressed the opinion that while the plates of the atlas were very unequal in their excellence, many were good, and that the textual part of the work was on the whole admirable and likely to be of greater utility than the atlas itself. A second German edition has now been called for, from which we judge that the work has met with appreciation. The new edition is increased in size, new plates have been added, and others superseded by better ones. The text has been revised, enlarged, and brought up to date in a highly praiseworthy manner, and we are constrained to repeat our former criticism that it is of greater value than the plates. The latter are doubtless useful so far as such representations can go, and we do not doubt that it would be impossible to produce, on a cheap commercial scale, more accurate coloured figures of cultural appearances which often essentially elude depiction. But of the text we can speak in much warmer praise. In its present form it is a mine of valuable information. It is highly condensed and hardly suitable for the beginner, but it is written by those who are masters of their subject and who have taken infinite pains to include in the work all that is essential to its right understanding. It is divided into two parts, General and Special Bacteriology. The part dealing with General Bacteriology is by Professor Lehmann and was alone included in the abridged English edition and this formed its most serious defect, since no detailed description was at hand to supplement the plates. In this edition the general part has been improved in many ways; in particular the chapter on Susceptibility and Immunity has been so enlarged and rewritten as to be a most valuable summary of our knowledge on the subject. The writer's views on specificity amongst bacteria are likewise to be commended. He admits the impossibility of absolute specific distinctions in many cases and groups the bacteria around the type-form (as "Haupt-art" and "Neben-arten") in a very luminous manner. The larger part of the text is devoted to Special Bacteriology; it is the joint production of the two authors and contains a sufficiently full account of all the important species hitherto described, with tabular schemes for their differentiation which should prove of great utility. We regret to note that in the copy supplied to us the disposition of the type on the page is at times so careless that the top lines are almost lost, while an excessive margin is evident below. But the text is legibly printed and misprints are practically absent.

LIBRARY TABLE.

Manual of Bacteriology. By ROBERT MUIR, M.A., M.D. Edin., Professor of Pathology in the University of Glasgow, and JAMES RITCHIE, M.A., M.D.Edin., Lecturer in Pathology in the University of Oxford. Second edition. Edinburgh and London: Young J. Pentland. 1899. Pp. xviii., 564.—It is more than two years since we reviewed the first edition of this work and we were then able to speak of it in very favourable terms. The appearance of a second edition affords us the opportunity not only of repeating our former verdict but of emphasising it. We have no hesitation in asserting that this book deserves to rank amongst the very foremost of the smaller text-books on bacteriology, and we know no work of the kind which we can more strongly recommend to the student or the practitioner. It is most ably and lucidly written, it is thoroughly accurate and reliable, and it is fully abreast of the times. The present edition, unchanged in its general scope and plan, is enlarged and improved in many ways. Amongst the many alterations the following may be noted. The section dealing with bacterial toxins has been enlarged and in part re-written, as has the chapter on immunity and antitoxins. The same is the case with the pages devoted to agglutination of the bacillus typhosus and other bacilli. Paragraphs have been added on the standardisation of the reaction of media, on bacterial fermentation of sugar and on indol formation, on the permanent preservation of cultures, and on vaccination against typhoid fever and bubonic plague. Malta fever, yellow fever, and other diseases now receive due consideration, as do also the diplococcus intracellularis meningitidis, the smegma bacillus, and Gärtner's bacillus enteritidis. Many excellent new micro-photographs have been added. The work is, in fact, admirably illustrated. It is, indeed, difficult for the reviewer to fix on any noticeable defect in the book. We think, however, that the bacteriological examination of water might receive more extended notice and we regret the absence of any detailed information on the all-important subjects of disinfection and antiseptics. We would also call attention to a singular slip in mathematics on p. 5, where it is stated that, assuming a bacterium to reach maturity and divide in half an hour, a simple calculation will show that at the end of 24 hours from one individual 17,000,000 will be produced. Two to the power of 48 is, on our computation, 281,474,976,710,656.

Chemical and Microscopical Aids to Clinical Diagnosis: being a Guide to Urinary, Gastric, and other Analyses Employed in Practical Medicine. By CARSTAIRS C. DOUGLAS, M.D., B.Sc.Edin. Glasgow: James Maclehose and Sons. 1899. Pp. xii., 258.—There is plenty of room for a little manual of this kind when it is clear, accurate, and well written, as in the present case. Methods of clinical diagnosis are becoming so numerous and important that they now form a very essential part of the student's curriculum, and this volume is small enough, yet sufficiently detailed, to satisfy modern teaching requirements. Dr. Douglas has brought together into a small compass all those methods of research which have proved of value in clinical diagnosis, including many of quite recent introduction, and he has taken pains to explain them. More than half the book is concerned with a consideration of the urine. Nor is this an undue proportion when we consider the large amount of work which has been devoted to its study. The other tissues and fluids of the body are, however, by no means neglected, and the book as a whole is well proportioned. Illustrations are introduced where necessary and they are clear and good. If we point out one or two errors or omissions it must in no way be taken to imply an unfavourable estimate of the work. There are a few obvious misprints—e.g., "coma" bacillus on p. 226, while on p. 182 the diameter of actinomyces threads is given as 5 μ. The writer, too, is amongst those who continue to regard the Finkler-Prior vibrio as the cause of cholera nostras. The directions for performing the serum test for typhoid fever are too short and incomplete, nor is the dilution of the serum recommended (1 in 10) sufficient to exclude fallacies. It is fair, however, to state that no pretence is made to include in the work a complete account of bacteriological diagnosis. In describing the preparation of blood films for staining purposes no mention is made of fixation by osmic acid vapour and we do not agree with the statements quoted on p. 200 that the nuclei of polymorphonuclear leucocytes take up acid dyes and that eosinophiles are "old cells." The "neutrophile" granules of Ehrlich are now known to be oxyphile. Starch, especially maize-starch, might have been mentioned amongst the misleading foreign bodies commonly found in urine. The distinction implied on p. 102 between hepatogenous and hæmatogenous jaundice does not commend itself to the modern pathologist. These and other minor defects can be remedied without difficulty. The book as a whole is singularly free from inaccuracies and can be recommended as a most useful, practical work to students and practitioners.

Dictionnaire des Termes de Médecine (Français-Anglais). By H. DE MÉRIC, M.R.C.S.Eng. London: Baillière, Tindall, and Cox. 1899. Demy 8vo, pp. 244. Price 4s. nett.—This is the French-English part of a dictionary of which the English-French portion has been separately and previously published, and was the more satisfactory of the two. In his preface the author remarks that he has been reproached for having inserted into the English-French portion of his dictionary words which had no place in such a work. We must candidly say that we think this, the second part of his dictionary, is open to the same objection. A dictionary of medical terms must necessarily include some words which are not always used in a medical sense; but we think the author has been a little lax in a number of the words which he has allowed to creep in. There is also much needless repetition of stem-words with adjectival and other terminations. On the other hand, the dictionary is wanting in many instances as regards symptoms, conditions, diseases even, and apparatus, frequently alluded to in French medical practice and literature, and in special terms to which reference might advantageously have been made. At the same time, the author deserves the thanks of medical men for his labour: so far as we know, there is no other French-English medical dictionary in the market, and, although the present work could be greatly improved, it will serve as a solid foundation for a fuller work in an edition to come.

JOURNALS AND REVIEWS.

Janus: Archives Internationales pour l'Histoire de la Médecine et la Géographie Médicale. Rédacteur-en-chef: Dr. H. A. PEYPERS, Amsterdam. Quatrième année, dixième livraison, 15 Octobre–15 Novembre, 1899. Onzième livraison, 15 Novembre–15 Decembre, 1899. London: Williams and Norgate.—These two parts of a valuable international journal—published in Amsterdam, Jena, Paris, and London—contain much instructive matter. Amongst the serial articles is a reproduction of John Locke's "Observationes Medicæ," serving to remind us of that philosophical physician and friend of Sydenham, one of the cases of measles recorded being that of the latter's son, "W. Sydenham, puer, 11 annorum." There are learned studies of Leprosy in Denmark in the Middle Ages by Dr. Ehlers of Copenhagen, and of the Pharmacopœia in the Seventeenth Century by Dr Landau of Nuremberg; but the English reader will perhaps be more attracted by the account given by Dr Henderson of Columbia Ohio, of "The Earliest Contribution to Medical Literature in the United States, the said contribution being a leaflet, by one Thomas Thacker, issued at Boston at the close of 1677 It is entitled, "Guide in the Small pox and Measles,' and consists, says Dr Henderson, of "a compendious English translation of a portion of the writings of Sydenham its publication being doubtless evoked by the prevalence of small pox in Boston at this period In the latest number of the journal is the opening of an article upon Tuberculosis and Climate, by Dr Gros, which is of value as showing the prevalence of this disease amongst the natives of Algeria The same number contains a portrait and brief memoir of the late Dr Theodor Puschmann who died recently at Vienna in his fifty sixth year

Revue de Gynecologie et Chirurgie Abdominale Vol. III, No 6 November December 1899 Paris. Masson et Cie — This number contains an interesting article upon Penetrating Wounds of the Gravid Uterus by Professor Estor and Professor Puech, the conclusion of his paper upon the Diagnosis and Treatment of Solid Tumours of the Ovary by M L Dartigues, the Treatment of Tuberculous Peritonitis by Laparotomy, by Professor J Galvani, and the usual analyses of current literature A bibliographical index and a name and subject index for the volume conclude the number

Annales de Gynécologie et d'Obstétrique Vol LII November, 1899 Paris G Steinheil —This journal contains the following original articles On Congenital Cystic Degeneration of Glandular Organs and especially of the Liver and Kidneys, by M A Couvelaire, the Rôle of the Toxin of the Gonococcus in the Gonorrhœal Affections of the Internal Genital Organs of the Female, by Dr V. Maslovski, and an Anencephalic Fœtus with Spinal and Facial Fissures, by Dr A Carache The usual bibliography concludes the number.

THE LANCET LABORATORY.

DIABETIC MARMALADE
(CALLARD AND CO 65, REGENT-STREET LONDON W)

ANY addition which is calculated to relieve the tedium of diabetic diet will be welcomed and we regard diabetic marmalade as an important introduction of this kind It is an attractive looking preparation with a pleasant orange flavour though it is somewhat sweet to the taste Our analysis showed that this sweetness was not due to sugar—indeed, we are able to state that the preparation is free from sugar On the other hand glycerine was detected but there was no saccharin Further examination showed that the consistence of the preparation was due in part to gelatin The marmalade contains finely cut slices of orange rind It affords a good adjunct to the diabetic dietary

GEROLSTEIN NATURAL MINERAL WATER
(THE GEROLSTEIN NATURAL MINERAL WATER CO 43, KING WILLIAM STREET LONDON E C)

The Gerolstein spring was discovered under somewhat peculiar circumstances, chiefly owing to the effects of escaping carbonic acid gas The spring is situated in the mountainous districts of the river Kyll which flows to the Moselle According to our analysis the composition of the water is as follows —Total mineral constituents 3 33 grammes per litre which may be divided as follows: carbonate of lime, 1·01 gramme per litre, carbonate of soda, 0 40 gramme, common salt, 1 52 gramme, and sulphates of the alkaline earths, 0 40 gramme The water is very pure, containing not a trace of organic matter It is impregnated with the natural carbonic acid gas of the spring We have before pointed out the distinct advantages of employing sparkling water which in no single respect contains an artificially added ingredient The mineral salts are present in agreeable proportion and the antacid properties of the water may be referred to the carbonate of soda and to the carbonate of lime dissolved in carbonic acid Probably calcium carbonate dissolved in carbonic acid gas is just as efficient as a neutraliser of acidity as carbonate of soda, with the further advantage that it is distinctly diuretic The water is well suited for blending It possesses a soft taste characteristic of naturally occurring ingredients It retains its sparkling property in a very satisfactory way and for a considerably longer period than do waters artificially charged

BYNOGLYCEROPHOSPHATES
(ALLEN AND HANBURYS LIMITED PLOUGH COURT LOMBARD-STREET, LONDON, E.C)

The glycerophosphates are of well known value in debilitated conditions and their combination with active liquid malt adds very much to their value in being associated with an enzyme which so materially aids in the digestion of farinaceous foods We found that the presence of glycerophosphates in no way retards the digestive action of the malt diastase Even in the cold, starch jelly quickly became a limpid liquid after the addition of a few drops of bynoglycerophosphates The preparation is quite agreeable to take and has a pleasant aromatic flavour suggestive of peach kernels Its therapeutic value under certain circumstances as in wasting diseases will be readily conceded

SAARBURG MOSELLE
(SAARBURG MOSELLE EXPORT CO LIMITED 2, BURY STREET ST JAMES'S LONDON S W)

We have paid some attention to the specimens of this wine submitted for examination because it is said to be specially suited for gouty and diabetic patients How far this is so may in some measure be seen from our analyses which were as follows 1893 Moselle extractives, 2 21 per cent, mineral matter 0 16 per cent, alcohol, by weight 8 64 per cent, by volume 10 73 per cent, equal to proof spirit 18 81 per cent, tartaric acid 0 51 per cent, acetic acid, 0 12 per cent, and sugar, 0 24 per cent 1895 Moselle extractives, 1 91 per cent, mineral matter, 0 15 per cent, alcohol, by weight 9 36 per cent, by volume 11 61, per cent, equal to proof spirit 20 35 per cent, tartaric acid, 0 55 per cent, acetic acid 0 10 per cent, and sugar, 0 17 per cent 1897 Moselle extractives, 1 96 per cent, mineral matter, 0 18 per cent, alcohol, by weight 9 26 per cent, by volume 11 61 per cent, equal to proof spirit 20 35 per cent, tartaric acid, 0 64 per cent, acetic acid, 0 098 per cent, and sugar, 0 19 per cent From these results it will be seen that these wines contain hardly any sugar, yet the alcoholic strength is low They belong to the class of light wines suitable particularly for moderate use in diabetes or where there is a gouty tendency They are delicate in character, without added spirit, non saccharine and practically non acid All the wines were in excellent condition with pleasant flavour and dry When a light stimulant is desirable in conditions where alcohol, sugar and acidity are to be avoided as much as possible these wines would seem to serve suitably for the purpose They are at any rate free from the drawbacks of heavy wines loaded with sugar and containing a high percentage of spirit Although these wines contain the normal acids of the grape yet they yield an ash which is markedly alkaline Thus their effect upon the blood would be to increase its alkalinity Saarburg Moselle affords an excellent beverage blended with aerated water but especially with a natural mineral water. The same wine might be supplied with advantage in sparkling form.

UROTROPINE (SCHERING).

(A. and M. Zimmermann, 9 and 10, St. Mary-at-Hill, London, E.C.)

Urotropine has received some prominence of late as a useful diuretic and solvent of uric acid concretions. It appears to be a compound produced by the action of formaldehyde on ammonia and is known shortly as formin. Its chemical name is hexa-methylene-tetramine. Urotropine occurs in colourless granular crystals exhibiting an alkaline reaction. It is soluble in water but sparingly in alcohol. It is stated that urotropine increases the excretion of the urine and of uric acid, the solution of the urates beginning within 24 hours of the administration of the drug. It is said also to serve as a urinary antiseptic and to be effective in many forms of cystitis. The dose is from five to 15 grains.

"FINO PURO" SHERRY (GONZALEZ BYASS).

(Hatch, Mansfield, and Co., 1, Cockspur street, Trafalgar-square, London, S.W.)

There are features in the results of the analysis of this sherry which imply that it is excellently adapted for dietetic purposes. Thus, it is practically non-acid in character, contains a minimum of sugar, and is of comparatively low alcoholic strength. The actual analysis was as follows: alcohol, by weight 13 92 per cent., by volume 17·17 per cent., equal to proof spirit 30 09 per cent.; extractives, 2 62 per cent.; mineral matter, 0 60 per cent.; sugar, 0 83 per cent.; tartaric acid, 0 43 per cent.; and acetic acid, 0 03 per cent. It is a light delicate wine and of a pale colour, belonging to that class of sherry known as Amontillado fino. It is a "brut" wine. It possesses excellent bouquet and flavour and is perfectly free from the heavy character of loaded wines. Indeed, its composition shows it to be of the lightest character amongst sherries. It is an agreeably stimulating wine, sound, and possessing the qualities of a pure natural sherry.

MISTURA FERRI SALINA (SELLERS).

(J. Sellers, 11, Clerkenwell-green, E.C.)

The convenience of this preparation is obvious. It is of a strength which by definite dilution yields a solution containing suitable administrative quantities of the various drugs which it contains. These drugs are ferri sulph., liq. arsenicalis, tinct. nucis vomicæ, and the alkaloids of cinchona bark. Our analysis has confirmed the presence of each and all of these medicaments. The mixture also contains the sulphates of soda and magnesia. The strength is such that one ounce diluted to eight ounces forms a suitable mixture for administration in doses of one ounce. We found the iron to be present intact in unoxidised condition. This formula is admittedly an excellent one in ministering to blood impoverishment, as in anæmia and chlorosis.

FINE OLD BRANDY (SPANISH).

(J. Wilson and Valdespino, 79, Mark-lane, London, E.C.)

More than once we have drawn attention to the fact that excellent brandy—that is, a genuine wine spirit—is imported into this country from Spain, the colonies, and elsewhere. It is notorious that since the unfortunate devastation of the French vineyards by the phylloxera scourge spirit described as genuine cognac has been imported into this country in increasing quantity. According to official returns it was not possible that this spirit could have been obtained during the distillation of wine, and evidence was given in favour of the spirit being derived from grain or other material. As we have pointed out some differentiation may be made by determining the amount of volatile ethers. Malt or grain spirit does not contain a trace of these interesting bodies since they are derived by the interaction of fruit acids during the process of fermentation upon the alcohol. The specimen under criticism, which comes from Spain, gives abundant evidence, assuming the presence of these ethers to be a criterion, of being a genuine wine-derived spirit. Our analysis gave the following results: extractives, 0 37 per cent.; mineral matter, 0 01 per cent.; alcohol, by weight 47 82 per cent., by volume 55 60 per cent., equal to proof spirit 97 44 per cent.; acidity reckoned as acetic acid, 0 06 per cent.; and alcohol in volatile ethers, 0 03 per cent. The spirit was characterised by a pleasant fragrance in regard to both taste and smell. According to these results we have little doubt that it is a genuine wine-derived spirit matured by storage and therefore well adapted for medicinal use. It is important that for clinical use care should be taken that only a spirit derived from wine and afterwards matured should be employed, because genuine brandy possesses restorative properties which cannot be referred to alcohol alone.

CITROPHEN.

(Fassett and Johnson, 31 and 32, Snow hill, London, E.C.)

Citrophen is a compound of citric acid with phenetidin. As is well known phenacetin (para-acet-phenetidin) has been used as an antipyretic and analgesic, but not always without after-effects of an objectionable kind, simulating the action of a poison and with the production sometimes of a rash. It is stated that when combined with citric acid, as in *citrophen*, all objectionable sequelæ are avoided while the analgesic and antipyretic properties are preserved. Testimony has been published of the value of citrophen in influenza, migraine, and other conditions where pyrexia is a feature. Citrophen is a white powder possessing a slightly acidulous taste and it possesses the advantage of being soluble in water. It is said to consist of one part of phenetidin with one part of citric acid in true molecular proportion. It is, of course, conceivable that the introduction of a complex organic molecule such as citric acid would sensibly modify the action of a quinine substitute like phenacetin, much as the naturally occurring morphine compounds differ in their action from the artificially prepared chlorides or sulphates.

CASCARA CHOCOLETTES.

(Wright, Layman, and Umney, 48 and 50, Southwark street, London, S.E.)

The feature of these preparations is mainly one of device, while the extract of cascara contained in the "chocolette" consists of the pure aperient principles of the bark. The tablets are chocolate-coated, attractive in appearance, and may be taken without any marked or objectionable taste of the drug asserting itself. The tablets are easily soluble in water at ordinary temperatures and they are very convenient for administration and satisfactory in effect.

MALTZYME.

(The Malt Diastase Company, New York, and 19, Cross street, Hatton garden, London, E.C.)

Maltzyme is evidently prepared with due regard to the preservation not only of the digestive principle of the malt but of the important nourishing constituents of the grain also. It is exceedingly active on starch jelly, rapidly converting it, even in the cold, into soluble starch and finally dextrin and maltose. At the body temperature its action is still more rapid. One important advantage of maltzyme is its thin consistence, so that the requisite dose may be readily poured out of the bottle. It possesses a fine malty flavour with no unpleasant after-taste. We have examined also maltzyme with cod-liver oil, a combination which, in view of the activity of the diastase, is a valuable therapeutical agent, especially in wasting diseases.

THE LANCET RELIEF FUND.

For Members of the Medical Profession and their Widows and Orphans when in Distress.

ALMONERS.

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.
THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.
THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.
THOMAS WAKLEY, F.R.C.S. Eng.
THOMAS WAKLEY, Jun., L.R.C.P. Lond.

HON. AUDITOR.

SIR HENRY PITMAN, M.D. Camb., F.R.C.P.

* * *

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, *in cases of Acute Distress and Emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation:—

> * "The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say: (*a*) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (*b*) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief."
>
> (*In the case of Widows and Orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.*)

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund") to the Secretary, Mr. EDWARD DAVIES, THE LANCET Offices, Strand, London, W.C.

The application should be accompanied by two separate testimonials, one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner, stating—that the application addressed to the Almoners has been read, how long they have known the applicant, and that they believe the statement to be perfectly truthful, and such as may be acted upon without further inquiry.

THE LANCET.

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. II. FOR 1899.

SEVENTY-SEVENTH YEAR.

EDITED BY THE PROPRIETORS:

THOMAS H. WAKLEY, F.R.C.S. Eng.,

AND

THOMAS WAKLEY, Jun., L.R.C.P. Lond.

LONDON:
PRINTED AND PUBLISHED BY THE REGISTERED PROPRIETORS, AT THE OFFICES OF "THE LANCET," No. 423, STRAND,
AND Nos 1 & 2, BEDFORD STREET, STRAND

MDCCCXCIX.

INDEX TO VOLUME II., 1899.

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Ancoats Hospital, Manchester.—Two cases of abdominal surgery (under the care of Mr. E. Stanmore Bishop), 91
Birmingham and Midland Eye Hospital.—Two cases of subconjunctival rupture of the sclera, with retroflexion of the iris without dislocation of the lens and with the subsequent retention of practically normal vision in each case (under the care of Mr. Henry Eales and Mr. Wood White), 412
Bristol General Hospital.—A case of primary sarcoma of the thyroid; thyroidectomy; relief of symptoms (under the care of Dr. J. Lacy Firth), 567
British Hospital, Buenos Ayres.—Two cases of acute rheumatism treated surgically (under the care of Dr. O'Conor), 95
Buff Bay Hospital, Jamaica.—Two cases of cut throat with opening of the air passage (under the care of Dr. Edward R. C. Earle), 1164
Butterworth Hospital, Cape Colony.—A case of multiple fibroma (under the care of Mr. J. H. Nankivell), 492
Christchurch Hospital, New Zealand.—A case of jaundice due to floating kidney; lumbar fixation; recovery (under the care of Dr. P. Clennell Fenwick) 1296
City Hospital, Birmingham.—Case of membranous angina and membranous vaginitis of a doubtfully diphtheritic nature occurring in a patient convalescing from scarlet fever and associated with an unusual erythematous eruption (under the care of Dr. C. Killick Millard), 1295
Cumberland Infirmary.—A case of perforated gastric ulcer and a case of strangulated hernia (under the care of Dr. R. Maclaren), 1094—A case of multiple fracture (under the care of Dr. H. A. Lediard), 1440
Derbyshire Royal Infirmary.—A case of icterus gravis (under the care of Dr. W. Benthall), 1588
Eden Hospital, Calcutta.—A case of rupture of the gravid uterus, abdominal section and removal of fœtus and universally adherent placenta, enterectomy; recovery (under the care of Lieut.-Col. Joubert, I.M.S., and Captain Hubert M. Earle, I.M.S., resident surgeon), 279—A case of Cæsarean section during labour for obstruction to delivery per vias naturales due to cancer of the cervix after considerable dilatation of the latter and rupture of the membranes had taken place; recovery of the mother and survival of the child for three and a half days (under the care of Captain Hubert M. Earle, I.M.S.), 1365
English Hospital, Huelva, Spain.—A case of œsophagotomy; the after treatment (under the care of Dr. W. A. Mackay), 1516
Fulham Infirmary.—Four cases of otitis media (under the care of Mr. Vaughan Pendred), 1363
Government Civil Hospital, Hong-Kong.—A case of exalgine poisoning, recovery after a very large dose (under the care of Mr. J. Bell), 830—A case of bubonic plague treated with large doses of carbolic acid; recovery (under the care of Dr. J. Mitford Atkinson, Principal Civil Medical Officer), 1589
Guy's Hospital.—Two cases of unilateral nasal diphtheria (under the care of Mr. C. J. Symonds), 785—A case of ruptured aortic aneurysm and gumma of the heart at 26 years of age (under the care of Dr. L. E. Shaw), 839—A case of carcinoma of the rectum; colotomy; death from suppression of urine of 21 days' duration (under the care of Mr. L. A. Dunn), 1663
Leeds General Infirmary.—A case of injury to the spinal cord (under the care of Mr. B. G. A. Moynihan), 840—A case of acute paralytic dilatation of the stomach (under the care of Mr. W. H. Brown), 1017—A case of traumatic (tuberculous?) meningitis (under the care of Mr. W. H. Brown), 1364
London Hospital.—A second case in which ligature of the uterine arteries was followed by arrest of excessive hæmorrhage and shrinking of a fibroid) under the care of Dr. G. E. Herman), 1094—Two cases of tumour of the vagina (under the care of *Dr. A. H. N.* Lewers), 1810
London Temperance Hospital.—A case of compound, comminuted, depressed, impacted fracture of the vault of the skull, wound of the dura mater; elevation by primary operation; recovery (under the care of Dr. W. J. Collins), 1017—A case of calculus vesicæ in a man, aged 53 years; suprapubic lithotomy, bladder sutured, catheter tied in for 12 days, uninterrupted recovery (under the care of Dr. W. J. Collins), 1295
Manchester Royal Infirmary.—A case of retro-peritoneal cyst and a case of hydronephrosis (under the care of Mr. Wright and Dr. Judson Bury), 215
Middlesex Hospital.—Two cases of papillomatous cysts (under the care of Mr. Pearce Gould), 490
North West London Hospital.—A case of congenital atresia of the bowel (under the care of Mr. J. Jackson Clarke), 568—A case of emphysematous gangrene (under the care of Mr. J. Jackson Clarke), 1229
Preston Royal Infirmary.—A case of rheumatoid arthritis (?); ankylosis of both elbows, excision (under the care of Dr. F. W. Collinson), 1230
Provincial Hospital, Port Elizabeth, Cape Colony.—A case in which lumbricoids were a cause of obstructing the small intestine; sequel to a case of alleged poisoning, necropsy (under the care of Dr. Donald M. MacRae, late resident superintendent), 786
Rotherham Hospital.—A case of volvulus of the small intestine; laparotomy, recovery (under the care of Mr. Reid), 829
Royal Albert Edward Infirmary, Wigan.—Two cases of traumatic epilepsy; trephining; recovery (under the care of Mr. R. H. Cowan and Mr. E. H. Monks), 1441—A case of tuberculous disease of the right knee and right epididymis; death under chloroform (under the care of Mr. William Berry), 1811
Royal Cornwall Infirmary, Truro.—A case of strangulated complete prolapse of the rectum released by abdominal section, ultimate cure of the chronic prolapse by anchoring the sigmoid to the abdominal wall (colopexy) (under the care of Dr. F. Harold Carlyon), 1664
Royal Free Hospital.—A case of partial enterocele, operation, recovery (under the care of Mr. W. H. Battle), 214
Royal Infirmary, Liverpool.—A case of puerperal septicæmia in which antistreptococcic serum was used with success (under the care of Dr. T. D. Grimsdale), 719
Royal Hospital for Sick Children and Women, Bristol.—Case of very acute diabetes in a boy aged five years (under the care of Dr. E. Leonard Lees), 1735
Rugeley District Hospital.—A case of severe multiple injuries; laparotomy; death in three months (under the care of Dr. W. L. Hubbard), 156
St. Mary's Children's Hospital, Plaistow, E.—A case of strangulated inguinal hernia, of cæcum and vermiform appendix, in a child six weeks old successfully treated by operation (under the care of Mr. E. A. T. Steele), 279
St. Mary's Hospital.—A case of gunshot wound of the abdomen (under the care of Mr. A. J. Pepper), 26—A case of sarcoma of the carotid sheath; removal of the growth together with portions of the carotid arteries, internal jugular vein, and pneumogastric nerve; recovery (under the care of Dr. Seymour Spicer and Mr. H. Stansfeld Collier), 342—A case of virulent acute rheumatism with extensive purpura, temporary improvement followed by death from cardiac failure; necropsy; microscopy (under the care of Dr. D. B. Lees), 1163
St. Thomas's Hospital.—A fatal case of poisoning by crystals of permanganate of potassium (under the care of Dr. Charles E. Box), 411—Case of tuberculous bladder greatly improved by hydraulic distension (under the care of Mr. W. H. Battle), 1587
Sheffield Royal Infirmary.—Three ophthalmic cases (under the care of Mr. Simeon Snell), 1735
Teignmouth Hospital.—A case of hydrocele of the sac of a femoral hernia (under the care of Dr. F. C. H. Piggott), 157
Victoria Hospital for Children, Chelsea.—A case of strangulated inguinal hernia in an infant, aged ten and a half months; operation; recovery (under the care of Mr. D'Arcy Power), 829
West Ham Hospital.—A case of ischiatic hernia (under the care of Mr. W. A. Grogono), 1734
Western General Dispensary.—A case of hernia through a congenital opening in an abnormal fold of peritoneum (under the care of Mr. W. D. Parsons), 1439
Western Infirmary, Glasgow.—A case in which a small silver coin was lodged in the larynx for four weeks; removal with forceps under cocaine (under the care of Dr. Walker Downie), 1018
Western Ophthalmic Hospital.—A case of *epithelioma of the conjunctiva; enucleation* (under the care of Mr. Arthur W. Wheatly), 719
Westminster Hospital.—A case of extensive gummatous disease around the femur and the hip-joint with chronic periostitis of the linea aspera; amputation; recovery (under the care of Mr. W. G. Spencer), 902—A case of extensive congenital and acquired heart disease (under the care of Dr. F. de Havilland Hall), 1514
Wolverhampton and Staffordshire Hospital.—*A case of acute hæmorrhagic pancreatitis* simulating intestinal obstruction; necropsy (under the care of Dr. E. Deanesly), 26

Three Drawings illustrating Description of a Case of Hernia through a Congenital Opening in an Abdominal Fold of Peritoneum (Mr. W. B. Parsons), 1439, 1440

Fifteen Figures, several of them half-page in size, accompanying paper entitled "Modern Military Bullets: a Study of their Destructive Effects" (Dr. A. Keith and Mr. H. M. Rigby). Figs. 1 and 2 consist of representations of the Mark II., the Mark IV., the Dum-dum, the Mauser, and the Martini-Henry rifle bullets, also the Webley and the Mauser pistol bullets. Figs. 3 and 4 show the effects produced by these bullets on bars of soap, and Figs. 5 to 15 inclusive the Effects produced on the Trunk, Lower Limbs, and Skull, 1500, 1501, 1502, 1503, 1504, 1505, 1506, 1507

Diagram showing Measuring Lines and Lines of Incision referred to in paper on Gunshot Wound of the Brain through the Mouth (Professor A. E. Barker), 1509

Drawing of a Transposed Heart, accompanying description of a case of Lateral Transposition of the Viscera (Dr. J. H. Brooks), 1513

New Cranial Osteotome worked by an Electro-Motor (Dr. F. W. Robinson), 1529

Whole Page of Tracings showing the Effect of Formic Aldehyde on the Frog's Heart, accompanying paper on the Influence on Health of Chemical Preservatives in Food (Mr. A. G. R. Foulerton), 1581

View of the Parts illustrating description of a case of Traumatic Aneurysm of the Carotid Artery caused by a Sewing Needle (Dr. E. H. Douty), 1584

Portrait of Capt. S. G. Moores, wounded in South Africa, 1615

Ten Engravings of Disorganised Kidneys, Specimens of Calculi, and Ureters containing Impacted Calculi, accompanying paper on Calculus in the Ureter (Mr. H. Morris), 1644, 1645, 1646, 1654, 1655, 1656, 1657

Radiogram of a Rare Form of Fracture of the Lower End of the Radius (Dr. J. B. Clarke), 1662

Diagrammatic Illustration (reduced one-half) of a Hat-pin Removed from the Stomach (Mr. J. Halliwell), 1732

Four Engravings of the Raston Bed rest and Pillow Support, 1745

Portrait of the late Sir Richard Thorne Thorne, 1763

Portrait of the late Capt. M. L. Hughes, 1766

Diagram of Part of a Pilgrim Camp, described in paper on the Measures taken at Tor and Suez against Ships coming from the Red Sea and the Far East (Dr. M. A. Ruffer), 1801

Six Diagrams of the Abdomen, accompanying paper on Early *versus* Late Operation in Cases [illegible]

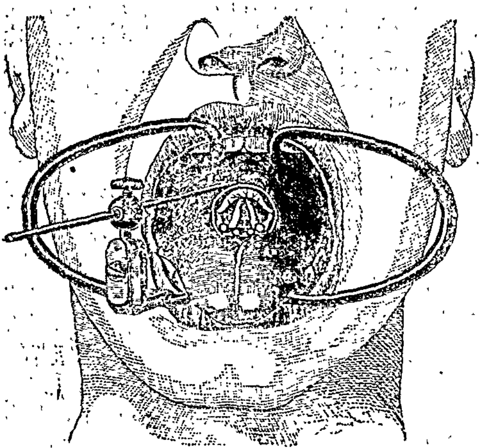
END OF THE SECOND VOLUME FOR 1899.

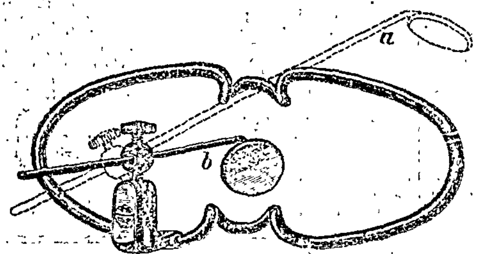
PRINTED and PUBLISHED by the REGISTERED PROPRIETORS at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, Jan. 6th, 1900.

New Inventions.

A NEW LARYNGOSCOPE.

THE instrument here shown, which has been already mentioned in our Budapest correspondence,[1] was devised by Dr. Mark Paunz. The advantage claimed over similar instruments is that being fixed it allows plenty of space for the instruments of the surgeon so that he can use both hands in performing intra-laryngeal operations. Dr. Paunz has also recently devised a similar instrument for retro-nasal operations. The illustrations show the instrument in position and two positions (*a* and *b*) which can be given to the mirror.





A SIMPLE APPARATUS FOR ADMINISTERING THE INTRA-GASTRIC NEEDLE-DOUCHE.

BY the intra-gastric needle-douche is meant the application to the interior of the stomach of very fine jets of water which impinge upon its walls with considerable force. By the use of hot and cold water in alternation a tonic effect is produced upon the gastric musculature which has proved of the greatest service in the treatment of atony and allied conditions. Moreover, it has been found in practice that adherent mucus is removed by the needle-douche with greater facility than by ordinary lavage. The inception of this valuable mode of treatment must be credited to Professor Turck of Chicago, who communicated it to the profession in a paper which he read before the Section of Medicine at the annual meeting of the American Medical Association held at

FIG. 1.

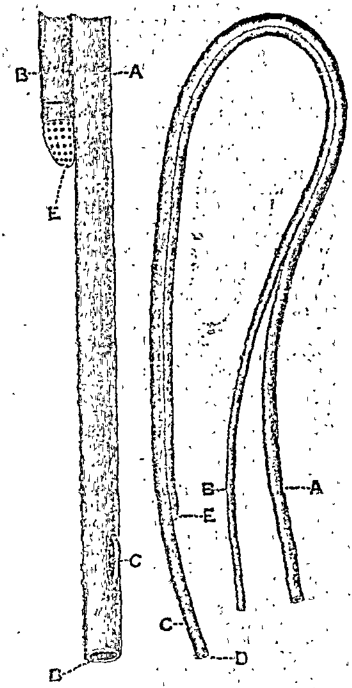


FIG. 2.

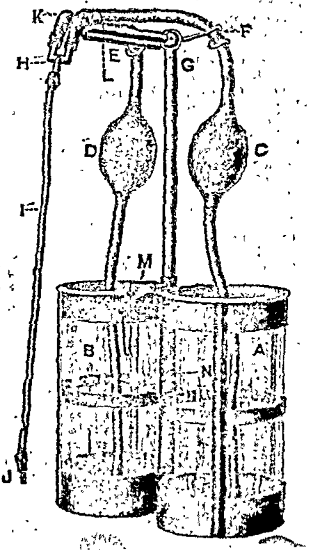

---

[1] THE LANCET, Oct. 28th, 1899, p. 1200.

Baltimore in 1895. His description runs as follows:—"For cleansing the stomach I use an apparatus which consists of a double tube—a short tube with a perforated ball at the end to be introduced into the stomach and a longer tube for the immediate return of the water introduced. The water is forced through the short tube under pressure and returned through the larger tube. ...... Not only does this apparatus cleanse the stomach, but it acts as a needle-douche, and as such is a vaso-motor stimulant."[1] Professor Turck's double stomach-tube (Fig. 1) consists of an efferent tube, A (shown at the left hand side of the illustration in its natural size) which is provided with a terminal eye, D, and one at the side, C. The afferent tube, B, is of smaller size and is cemented to A for the greater part of its length. It terminates in a conical perforated bulb shown at E. This bulb is of metal, and is provided with a shoulder which enters the end of the rubber-tube, to which it is further made fast by a silk thread shown in the sketch as a black line. The tube, E, is so arranged that it terminates about four inches from the end of A. The afferent tube, B, is connected by a suitable mount with the apparatus containing the water under pressure and the efferent tube, A, with an exhausting arrangement to be presently described. (I would here mention that I wish it to be distinctly understood that I do not claim to have made any improvement in Turck's double tube, which is practically perfect, but I figure it here for the sake of those of my readers to whom it may not be familiar.) Unfortunately it has to be procured either from Tiemann of New York or from Truax and Greene, Wabash-avenue, Chicago, as in this country we are so far behind America and Germany in the intra-gastric treatment of stomach affections, that it has not hitherto been worth any manufacturer's while to lay down the plant for making it. Professor Turck's original apparatus for forcing water through this tube consisted essentially of a couple of large glass wash-bottles, into which air was forced by means of a hand bulb. Whilst admirably adapted for use in the consulting room, the chief disadvantage of Turck's apparatus is its want of portability, and as in most cases it is essential that the needle-douche should be applied before breakfast, an apparatus is required which can be carried to the patient's house. I claim for my apparatus, which was exhibited in the section of Pharmacology at the Portsmouth meeting of the British Medical Association in 1899, that it is extremely compact and portable, that it is cheap, and that it can, on occasion, be extemporised from a couple of Higginson syringes, and that it is quite as efficacious as the more complicated apparatus in giving a needle-douche of sufficient force when used with a Turck's tube.

My apparatus for administering the intra-gastric needle-douche (Fig. 2) consists of a metal stand holding two glass cylinders, A and B. In each of these is placed a Higginson's syringe, C and D, the afferent tubes of which passing through specially designed spiral supports, E and F, upon the handle, G, are attached respectively to the limbs of the **Y**-piece H. From the third limb of this **Y**-piece proceeds a rubber tube, I, which terminates in a conical nozzle, J, of such a size as to enter the end of the smaller stomach-tube—that carrying the perforated ball. The handle, G, is attached to the upper end of a telescopic rod which, for portability, is made to shut down into the apparatus, and when in use is maintained at the proper height to keep the tubes of the Higginson's syringes straight or extended by means of a split pin, M, which enters a hole in the stand. The handle, G, is further provided with metal clips at K and L to hold the tubes in position. The nozzle, J, is corrugated in order that it may not slip out of the rubber stomach-tube, and the afferent tubes of the Higginson syringes are best provided with suction discs by means of which they may be fixed to the bottoms of the glass cylinders. Either the glass cylinders themselves or the central rod of the stand is graduated in ounces in order that an idea can be formed as to the amount of fluid which is being introduced into the stomach of the patient.

I believe that Professor Turck's original idea was that the longer or efferent stomach-tube should be attached to a long rubber-tube which passed to a pail or receptacle upon the floor, and that as soon as a few ounces of water had been introduced into the stomach syphonic action should be established by any of the usual methods. Thus, theoretically, the stomach ought by syphonage to keep itself empty. In practice, however, I have not found this practicable, and I believe that Professor Turck himself uses an exhausting bottle to empty the stomach at intervals whenever it appears to be getting full. In my own practice I use a very simple device which combines the advantages of syphonage with Turck's aspirating bottle. Upon the floor I have standing a large three-necked bottle, each neck being closed with a perforated cork. Through one of these corks passes a long metal tube which reaches nearly to the bottom. The upper end of this tube, which projects above the cork, is attached by a length of rubber-tube to the efferent stomach-tube. Through the second cork passes a short length of tube which carries on its upper extremity an exhausting bulb—that is to say, a rubber bulb which exhausts when it is worked. This is exactly similar to the bulb on a Higginson syringe working backwards. Through the cork in the third neck passes a short tube which carries at its upper extremity a tap. The apparatus works in the manner to be presently described.

In administering an intra-gastric douche hot and cold water are placed in A and B respectively and the apparatus is placed upon a table at a convenient height opposite to the patient, who sits upright in a chair. The double stomach-tube with its efferent tube, connected by a short glass tube and a long rubber one with the bottle which I have just described, lies ready upon the table in front. The exhausting bottle aforesaid is standing under the table. The stomach-tube is then passed and the conical mount J inserted into the smaller tube. If pressure be now made upon the bulbs C and D alternately, hot and cold water respectively will be forced into the stomach of the patient in the form of fine needle-like jets from the perforated bulb at the extremity of the shorter stomach-tube. In practice it is convenient to send in one quarter of one cylinder before proceeding to the other. The patient will thus get eight alternations of hot and cold water during the *séance*. At intervals the stomach is emptied of the water which has passed into it. A few compressions of the exhausting bulb attached to the bottle under the table will so rarefy the air in it that fluid from the stomach will commence to flow into it. As soon as this occurs the tap connected with the tube passing through the third neck may be opened, air will enter the bottle, and the flow will continue by syphonic action alone until the stomach is empty. We thus avoid the possibility of injuring the stomach wall by too strong suction. When it is borne in mind that according to the dynamometer the grasp of the hand is capable of exerting a pressure of about 120lb. it can be easily seen that sufficient force is generated to project jets of quite sufficient intensity to give a very efficient needle-douche in the stomach. In this form of apparatus clips or valves upon the tubes are quite unnecessary, as from the construction of a Higginson syringe backward flow is impossible. The apparatus is manufactured by Messrs. Bailey and Son, 38, Oxford-street, W.

GEORGE HERSCHELL, M.D. Lond.

Wimpole-street, W.

SEAMEN'S HOSPITAL FOR CARDIFF.—At a meeting of the committee of this institution held recently under the presidency of Sir Thomas Morel it was stated that up to the present £21,279 had been received. A piece of land of the value of £250 which adjoined the proposed site of the hospital was presented by the directors of the Taff Vale Railway Company.

PRESENTATIONS TO MEDICAL MEN.—On its becoming known that Mr. James Charles Weld, L.R.C.P. & S. Irel., of Hopetown, Victoria, Australia, was about to leave the town and district after a residence there of seven years or practically since the infancy of the town and district, his friends formed a committee with the view of making him a presentation. Subscriptions for this object were freely given, and at a social entertainment held in the Mechanics' Hall on Nov. 18th last Mr. and Mrs. Weld were presented with a marble clock, a silver claret jug, and a purse of sovereigns as tokens of the regard in which they were held by the inhabitants of the whole district from Warracknabeal northward.—At a crowded meeting held at Zion Chapel, Cwmavon, Glamorganshire, on Dec. 16th, 1899, Mr. Richard Thomas Williams, L.R.C.P. & S. Edin., L.F.P.S. Glasg., was presented with an illuminated address and a purse containing £120 as a mark of respect and esteem on the occasion of the termination in his favour of the charge made against him at the last meeting of the General Medical Council.

THE LANCET.

LONDON: SATURDAY, JANUARY 6, 1900.

THE medical life presents now so full and varied a programme that it is impossible when standing on the threshold of a new year either to pass in review in exhaustive manner the events of the year gone by or to forecast what will be the important developments of the year to come. In our *Annus Medicus* we strive each year with the former task; but in our opening words this week we make no effort towards the latter. Our position, however, with our readers, we are proud to think, asks for a few words with regard to THE LANCET in its relations to the medical profession. These relations are of such a character as to call from time to time for an account of our stewardship. It is our aim to make THE LANCET in the fullest sense the organ of professional opinion and the just reflection of professional sentiment, and in our endeavours to this end we incur a double responsibility towards our readers. Not only do we propose to furnish them from week to week with information and news, whether of a scientific or domestic character, that should be interesting to them, but we also record the feelings of the profession upon the various matters which come successively into prominence, while we accept the grave responsibility of suggesting the course that it would be wisest and best for practitioners to take in the many situations of delicacy and difficulty which present themselves in their public or private lives. Of this, one of the most difficult branches of our editorial work, it does not become us to speak much, but we do not hesitate to repeat what we have often said before, that it is the knowledge that we possess the trust of our professional brethren which gives us confidence as well as pleasure in facing the duties of 1900. So long as we receive from the profession the continuous support which has for more than three-quarters of a century been extended to us, so long we shall have warrant for believing that we have not failed to justify our claim to represent the best interests of the medical man.

The readers of our columns will know without having it pointed out to them that the year just passed has witnessed no sensational development of scientific therapeutics. Nothing comparable in its revolutionary effects upon diagnosis or treatment to the discovery of the x-rays or of the antitoxin treatment of diphtheria has been reported, and such advance as has occurred, though very real, has not reached any definite stage at which it would be convenient to say, Here is progress. New territories have been reconnoitred, but it cannot be said that there has been any effective occupation of them. The main efforts of investigators have been directed at increasing our knowledge of preventive medicine rather than at the attempt to discover new curative measures; and in an extended and rapidly extending familiarity with tropical disease we see an excellent example of fruitful work, nearly all of a preventive nature. This is the work which constitutes the chief claim of 1899 to have enriched the medical knowledge of the world. In THE LANCET will be found accounts of the diseases that are rife in the most distant parts of the earth, and all these communications to our pages are instinct with the authors' desire to afford trustworthy information whereon the scientific investigator can sit in judgment and from which he can make deductions. We regard the feeling of the community—quite a new feeling, by the way—that the public health of our colonial possessions is of the first interest to our Imperial position as a proper recognition of the position of medicine and a distinct gain to the profession, while the manner in which medical men have responded to that feeling redounds to their credit. At the present moment in many quarters of the globe investigations are being carried on in the best spirit of scientific zeal. Such work can only lead to substantial results for the good of the world; but it must not be forgotten either by the reader or by the worker that every apparent discovery must be submitted to probationary tests, and that the severer those tests the quicker will be the progress in the right line.

In the social, as distinguished from the scientific, world of medicine there has been activity, and this, which has been very generally manifested, appears to us to have been better directed than on previous occasions. The phrase "Medical Reform" has not been so often used as an elusive title to declamatory articles against the supineness of highly qualified persons or in recommendation of purely Utopian schemes. In many centres of England definite attempts have been made towards obtaining the concurrence of the medical men in the localities with some uniform scheme by which they can resist unfair encroachments upon their time and work, and thus will be enabled to devote their best energies to the welfare of the sick. The organisation of the profession into anything like an effective body for the protection of itself and of those who are its proper charges is yet a long way off, but we see signs in every direction that the efforts which are being made towards this desirable end are sensible and will bear fruit. The investigations of our Special Commissioner have played no inconspicuous part in transforming ill-directed disaffection into a more general movement against recognised grievances. They have supplied those who are determined to fight in constitutional manner for their own hands with dates, details, and figures, so that they are able to demand justice reinforced by incontestable argument instead of relying on rhetorical declamation. We have not finished our part of the task. There are many places where the evils of hospital abuse press hardly, and where the battle of the clubs is still being fought, concerning which we have as yet made no report. But the grievances that have been exposed are no longer denied and the amount of success in combating them that has attended concerted measures here and there is of good omen. The row may be a long one, as the South American proverb would express it, but we ask our readers to help us in hoeing it by giving us all information that will be useful to their colleagues. The General Medical Council is now thoroughly alive to the fact that the medical profession intends that its interests, which after all are the interests of the public, shall be properly watched, and that measures shall be taken to amend the law in directions where the law has failed. The Direct Representatives of the profession on the Council are pledged to help their constituency to obtain the proper treatment that is implied by adequate protection against encroachment; and although they propose to do this in somewhat different ways each is animated with the desire to do justice to the confidence that has been reposed in him, and none will let slip any opportunity that his office gives him to advance the well-being of the general practitioner.

In any consideration of political possibilities the general outlook of affairs must play a part, and it is our duty to warn those of our readers who have looked confidently forward to "something being done soon" that the South African War will assuredly be a set-back to their expectations. This campaign has now reached a stage at which not the most experienced statesman, the most war-worn general, or the most astute wire-puller, will venture to prophecy much of what is to happen, but whatever the next events the end will not be soon. This means that Imperial Parliament will be fully employed for some time to come in dealing with questions arising out of the war and ranging from the price of condensed milk to the form of a new constitution for South Africa, and thus all domestic legislation will have to take slender chances in approaching sessions. GOD grant that all will come right and without any fearful loss of life, and that when next we address our readers upon the threshold of a New Year the national circumstances may warrant us in wishing them a happiness which cannot at the present juncture be theirs. In the meantime to the medical profession the bright spot in the gloomy sky is the universal and unstinted admiration that the medical branch of the services has won for its effective organisation, and the courage, skill, and resource of its members.

THE General Medical Council is so much in evidence in connexion with medical education that the use of its disciplinary or penal function is apt to be too little regarded. The number of practitioners whose conduct exposes them to the exercise of this function of the Council in any given year may almost be counted on the fingers of one hand. Only two registered practitioners—one a dentist—were removed from the Registers at the recent meeting, and they were erased on the ground of conviction in a criminal court and not as the result of an investigation into professional conduct by the Council. But the number indirectly affected by the disciplinary action of the Council is large. In the report of its Medical Aids Committee received by the Council a letter was read announcing that the London and Manchester Assurance Company had ceased to take new members into their medical aid department, thus meeting the objections of the Council as expressed in its resolution of June last against the practice of systematic canvassing and advertising for the purpose of procuring patients. The number of medical men under agreements with this company was about 1000. It is important therefore to give separate attention to the disciplinary work of the Council. Evil is often wrought by want of thought, and many of the practitioners who appear before the Council on a charge of irregular or unprofessional practice do so rather from inattention to the published resolutions of the Council than from any intention to go contrary to its wishes. It is remarkable that in spite of the large numbers of medical men associated with companies in which medical aid business has been carried on no actual charge against any individual practitioner has hitherto been brought. This does not show that the resolution of the Council has been ineffective. The action of the London and Manchester Assurance Company shows the contrary to be the case It is to be inferred that the companies have been moved to such action by their medical officers representing the risk to their interests involved in such a commercial way of getting patients. We need not say that it is far better that the General Medical Council should effect its object by the simple process of a general expression of strong disapproval of a system than by penal action against individual practitioners. It may easily be supposed that the London and Manchester Assurance Company is not the only one whose medical officers are affected by the resolution of the Council in June last. Time will show this. The profession at large will be glad if the effect of the Council's resolution on this subject is to bring about the discontinuance of what looks very like the carrying on of a sort of medical practice by commercial companies on commercial methods and principles.

The cases which were brought before the Council at its late meeting for its judicial consideration illustrate one or two points in reference, first, to the profession and, secondly, to the Council's own power, of which we ought to take note. A most glaring defect in the Council's power was made painfully manifest. For some time the Council has been accustomed to remove from the Register the names and qualifications of practitioners who were proved to have employed unqualified assistants and allowed them to attend grave cases as if they were registered practitioners. The scale upon which this practice obtained before the Council began to regard it seriously with a view to its being declared an offence involving erasure was very large. In some instances the offence is committed on a comparatively small scale and the *Council erases the* practitioner's name with the clear intention of restoring it to the Register after a time—long enough to be a warning to him and to others not to repeat the offence. In most instances there is no difficulty in the process of restoration. But in the case of a practitioner holding only the Licence of the Society of Apothecaries of London the difficulty is insuperable. At least this is the opinion of the legal adviser to that body, whose conception of the law is that the Society is bound to remove from its list any name which has been erased from the Register and has no power to restore it though the General Medical Council should be of opinion that the time had come for restoring the practitioner to his place on the Medical Register. This is a complete deadlock, and one which cannot be too seriously considered by Licentiates of the Society of Apothecaries who hold no other qualification as well as by the General Medical Council. It enables the Society of Apothecaries to inflict a permanent disqualification for a comparatively slight offence where no such punishment can be justified. Such a reading of the fourth section of the Apothecaries Amendment Act of 1874 seems to us to be forced and illogical. This section is plainly meant to enable the Society to follow the disciplinary action of the General Medical Council. The Society does so in the matter of erasure and declines to do so or asserts a *non possumus* in the matter of restoration, which is an absurd state of matters, converting a temporary into an eternal punishment and giving the Society of Apothecaries a penal power beyond that of the General Medical Council. Pending the correction or the different construction of the law those who depend for their claims to registration on the Licence of the Society of Apothecaries may well be careful to avoid the risks of erasure.

We have space to notice but one more fact—that at the recent meeting only two cases of unprofessional conduct pure and simple were brought under the notice of the Council. In one the practitioner—whose case had been investigated by the Council in June last and the decision in which had been suspended for six months—reconsidered his position and entirely satisfied the Council. The Council did not find him guilty of infamous conduct and the case against him came to an end. In another a charge of wrongful employment of an unqualified assistant was not supported by evidence satisfactory to the Council and the case against the practitioner failed. On the whole the inference is that the Council uses its penal powers discreetly and fairly and is entitled to have them more clearly defined and strengthened Such strengthening is the end of the clauses elaborated with so much care by Sir WILLIAM TURNER for the amendment of the penal sections of the Medical Act.

FROM the year 1837, when the Registrar-General's Office was established, down to 1874 the duties of the Registrar-General were almost exclusively administrative. When a new Government office is brought into being, however urgent the needs may have been which caused its creation, its duties will always require definition. There are things which it can do and things which it cannot do; there are duties which might belong to it if they were not already allocated to other departments; and the range of work, it will be found, cannot properly be estimated until the new department is actually in being, when its powers will more or less gradually be revealed to it. Then questions arise as to whether that range is large enough or too large, while the domestic side of its affairs and the scale of wages have to be settled. All this was done and done well in the Registrar General's office from the beginning, as was the statistical work within its limits. But in 1874 the whole scope of the department was altered, for in that year the duty of certifying the cause of death of their patients was imposed by statute upon medical men. The Registrar-General was immediately brought into close relationship with the medical profession and a large amount of medical knowledge became necessary to the proper interpretation of the figures received at Somerset House. This relationship has become more intimate year by year, until it is no exaggeration to say that, whether he be a medical man or no, the duties of the Registrar-General at the present time are essentially of a medical nature.

The most onerous of these duties, for example, involve considerations of statistical importance which cannot be adequately dealt with otherwise than by a person possessing medical knowledge and experience. The Registrar-General has to organise and maintain in efficiency the registration service of the country, and to do this he has to instruct the various local registrars, some 2000 in number, in the attitude that should be adopted towards medical men, towards coroners, and also towards the relatives of deceased persons from whom it may be necessary to obtain the particulars required for registration in the absence of a medical certificate. Part of this work may be called purely administrative, but we venture to think that it is the unimportant part, while it is also the part which has been brought by years of well-directed routine to a position where the things to be done are done automatically The vital part of the work is purely medical, for only a medical man can appreciate at their proper value the difficulties which at any moment may arise in a delicate matter of death registration. Again, the Registrar-General is responsible for the accuracy of the national death registers. This means that he must secure the careful examination and, where needed, the correction of every one of the half million certificates of death which are registered yearly in England and Wales, copies of which are sent to the central office for abstraction and compilation. Again, we venture to say that, given efficient organisation, the essential part of this work is medical and calls for medical knowledge of the highest order. For not only is the Registrar General required, if he is to discharge his duties properly, and at first hand, to be familiar with medical phraseology, but he must also be well versed in the probabilities of disease, so that the exact significance of a certificate or of any group of certificates may be present to his mind as quickly as the documents meet his eye. The Registrar-General also prepares weekly, quarterly, annual, and decennial medical reports of mortality dealing with the cause of death in every part of the country. This is probably the most valuable of his highly valuable labours and can only be discharged by a medical man. The Registrar-General who is not a medical man can only follow the lead of a superintendent of statistics possessing the qualifications which he is without. For the value of the statistical information in these reports would be *nil* if the lessons taught by the figures were not interpreted through the medium of medical learning. Figures unchecked by knowledge would first be wrongly arranged and then wrongly interpreted, and the lessons to be derived from them would be worse than useless for they would be absolutely false. These are the figures which upon proper presentation through a medical statistician warn the public of the occurrence of an epidemic of disease in any locality in England and Wales, giving notice of the fact to the proper departments of the State and so forming a safeguard to our national health. For these figures are relied upon not only by the Local Government Board [illegible] every medical man in [illegible] Kingdom [illegible] whether connected with that Board or acting on his private initiative as the guardian of the health of his locality. The Registrar-General is required also to conduct statistical investigations for the various State departments, for Royal Commissions, and for Committees of both Houses of Parliament, and upon his figures questions of legislation directly turn. His statements are not checked by others, but are accepted as authoritative information culled from an unimpeachable source and upon them amendments of the law of the land may directly ensue. It is unnecessary to point out how urgent it is that figures fraught with such issues should be placed before our legislators in a form which actually represents their meaning; and no one but a medical man can do this. The Registrar-General also gives statistical estimates and other information necessary to medical officers of health for the compilation of population estimates and for reports on mortality, sickness, and the incidence of epidemics: no one but a medical man can do this. Lastly, he is the officer responsible for the taking of the Census of England and Wales. The Census reports are utilised for the preservation of the public health, for the administration of the Factory Acts, and for the exigencies of the labour department of the Board of Trade, as well as by medical officers of health throughout the country, so that it must be his constant endeavour to arrange the details in a manner in which they may best serve their various purposes. And no one but a medical man can do this.

We have said enough, we think, to show that the duties which the Registrar General is called upon to perform are so thoroughly medical that when the medical part is subtracted little but official routine remains. As a matter of fact, the work that is now performed by the Statistical Superintendent, who is and must be a medical man, has become the essential work of the Registrar-General's Office, and we feel strongly that it is bad policy and bad economy that the essential work of the department should be performed by a subordinate. The duties which we have enumerated above, inasmuch as they are the chief care of the head of the department, should be personally attended to by the head of that department and consequently by a medical man. We understand that it is probable that Sir BRYDGES P. HENNIKER will shortly resign his post as Registrar-General. When this is the case we trust that the considerations which we have put forward will prevail in the selection of his successor. The brilliant results which have followed the appointment of Dr. WHITELEGGE as Chief Inspector of Factories of the Home Office should encourage the Government in placing a medical man at the head of a department where the work is almost exclusively medical in character.

THE list of examinations in general education recognised by the General Medical Council has undergone a few modifications which came into force on Jan. 1st. We are pleased to see the erasure of the "*second*-class certificate of first or second division of the examination of the College of Preceptors," and also of the "preliminary examination for medical students" at the same institution. The Council has also wisely recommended that the preliminary examination of the Royal Colleges of Physicians and Surgeons in Ireland should be discontinued. To all of us who are desirous that the preliminary examinations for entrance into our profession should not run below a due minimum these changes are most satisfactory, but do they go far enough? The required subjects are English language, Latin, mathematics (including Euclid, Books I., II., and III.), and Greek, or some modern language, and it is only in the past few years that it was necessary for the student to pass in these subjects at one time. On looking over the recognised list of examinations we still find junior, lower, and middle grade examinations included, and it is well known that in some of the examining bodies the standard is still none too high. The Education Committee of the General Medical Council has recently sought the assistance of experts in the general education of this country, and a more pitiful account of its average character can scarcely be imagined than that presented in the report of the Committee to the Council at its recent session. The experts consulted were the Rev. T. W. SHARPE, Professor W. S MCCORMICK, and Dr. J. MCGRATH, as being thoroughly conversant with the condition of secondary education in England, Scotland, and Ireland respectively. Their unanimous report is as follows, and we trust it will attract the attention of the school authorities in the three divisions of the country:—

"We have considered the question whether the senior and higher grade examinations should be substituted for junior Taking into account the present state of secondary education in the country we see *no possibility* of enforcing such a requirement in the near future. A demand of this kind would certainly result in defeating the end which the General Medical Council have in view. Either it would diminish to an indefinitely large extent the number of candidates entering the profession, or it would compel the examiners to a laxity of marking and a depreciation of the standard of questioning, which would merely have the effect of lowering the senior papers to the level of the junior papers. The standard of the medical preliminary examination must depend upon the general standard of the secondary education of each country in which the examination is held, and a standard too high for one might be found too low for another. We think, however, that the immediate object of the General Medical Council would be gained by the gradual raising of the standard of the lower 'junior' examinations to the level of those 'junior' examinations which in our opinion rank highest."

We can scarcely believe that the abolition of junior grade examinations would diminish to an indefinitely large extent the number of candidates entering the profession, and the suggestion that educational bodies would only depreciate their standard from a senior to a junior level is surely too severe a statement to make of our examination boards and one that can hardly be justified. It is obvious, however, from the discussion at the General Medical Council that any important reform in the general education of the medical student will be postponed for years and that the existing minimum standard is due to the kind of education which scholastic experts admit to be still in vogue in the secondary education of our scholars in the respective divisions of the kingdom. Individual communications to the examining bodies as to the improvement of their scope and standard can only be regarded as a futile waste of time and energy until the conditions which have now been published shall have been altered,

Annotations.

"Ne quid nimis."

THE LATE SIR JAMES PAGET.

ALMOST coincidently with the close of the year 1899 came the life's end of one of the foremost figures in the world of medical science which this century has produced. We speak elsewhere in full detail of the life and work of James Paget, but we may here express our intimate *sense* of the loss which the profession has sustained. By his wonderful insight into the various processes of pathology, by his power of storing up details and his faculty for comparing one with another he rendered incalculable service to the science of medicine and so to suffering humanity. His influence as a teacher was always for good, and the great hospital in which he took such an interest, within whose walls he did such admirable work, has never, since the days of Rahere, had a more faithful or upright servant.

THE NEW YEAR HONOURS.

THE list of New Year Honours although containing no names of very special distinction yet brings into prominence many of those who have done and are doing unobtrusive work for the Empire. Among the new Knights are the names of Mr. T. Lauder Brunton, M.D. Edin., F.R.S., and of Mr. F. H. Lovell, C.M.G., Surgeon-General of Trinidad. The work of Sir Thomas Lauder Brunton with reference to Pharmacology and Therapeutics and his services in connexion with the Hyderabad Chloroform Commission, on which he represented THE LANCET, are well known to our readers. As a physician of high standing and as a man who has unobtrusively worked hard in the profession to which he belongs the distinction that has been conferred upon him will be received with cordial satisfaction by all who know him. Sir Francis Henry Lovell, who is a member of the Executive and Legislative Council of Trinidad, at one time held the appointments of chief medical officer, President of the General Board of Health, and member of the Legislative Council of Mauritius. The Honourable John Alexander Cockburn, M.D. Lond. and Adel., formerly Premier of South Australia and now Agent-General in London for that colony, is made a Knight Commander of the Order of St. Michael and St. George, and four other members of the medical profession have been appointed Companions of the same Order—namely, Mr. John Pringle, M.B., C.M. Aberd., who is a member of the Privy Council and Legislative Council of the Island of Jamaica; Mr. Patrick Manson, M.D., LL.D. Aberd., who, as medical adviser to the Colonial Office, has done not a little in the cause of tropical medicine; Mr. Wordsworth Poole, M.B., B.C. Camb., the principal medical officer of the West African Frontier Force; and Mr. Archibald Donald MacKinnon, M.D. Aberd., principal transport officer for Uganda. Although not members of the medical profession the Right Hon. Sir John Lubbock, F.R.S., who has been made a peer, and Captain Abney, C.B., F.R.S., who has been promoted to Knight of his Order, have done work which bears both directly and indirectly upon medicine and public health. Captain Abney in particular has by his researches into the nature of light and its phenomena, embracing the physiology of vision, rendered great service to our profession. We congratulate all these gentlemen in the name of medical science.

THE ROYAL INSTITUTION OF GREAT BRITAIN.

THE list of Friday evening lectures to be delivered at the Royal Institution before Easter gives promise of a very interesting and instructive session, and among the lecturers will be Signor G. Marconi who on Feb. 2nd is announced *to deliver a lecture on Wireless Telegraphy.* In the list of subjects which have some connexion with medicine we note that Professor J. Reynolds Green will deal on Feb. 9th with "Symbiosis and Symbiotic Fermentation"; Major Ronald Ross, I.M.S., on March 2nd will lay before his audience some information with regard to Malaria and Mosquitoes; Professor Frank Clowes will on March 9th discourse on "Bacteria and Sewage"; and Professor J. Arthur Thomson on March 30th will discuss the "Facts of Inheritance." On Thursdays, Jan. 18th, 25th, and Feb. 1st, Dr. W. H. R. Rivers will deliver three lectures on "The Senses of Primitive Man."

THE LANCET RELIEF FUND.

THE report made this year by the almoners of THE LANCET Relief Fund carries on in a very remarkable way the thread of last year's report and enables us to refer to it as confirming the inferences which we then drew from what seemed to be settled features of the administration of the Fund. We had last year to remark that the benefactions showed a reduction both in number and amount and that there was a marked tendency for the benefits to take the form of gifts rather than of loans. Save as to the reduction in the number of benefits these observations apply equally to the facts disclosed by the present report. It happens, curiously enough, that the number of benefits is precisely the same this year as last, but on this occasion only one case has taken the shape of a loan, the rest have all been out-and-out gifts. We have, therefore, a broader basis to-day than we had 12 months ago for the pleasing deduction that the pressure of necessity upon those of our professional brethren and their immediate dependents who have fallen upon evil times is sensibly less acute than it was when the Relief Fund was founded. Coinciding as this improvement does with *improved conditions of* general prosperity it may be reasonably referred to this more general improvement as its cause and looked upon accordingly as a real, not merely as an apparent, amelioration in the condition of those of our fraternity upon whom the times press hardest. The singular, if not quite absolute absence of applications for loans points in the same direction and this is the more marked in the present because attention was expressly drawn last year in our columns to this feature of the almoners' work and we then pointed out that of the various cases which are presented for consideration there is none in which it is possible to extend a helping hand with a livelier sense of satisfaction than the case in which a timely loan helps a brother overtaken by adversity to help himself. That, however, is no great matter. The feelings of the benefactor do not count in comparison with the advantage of the beneficiary, and we hope with much confidence that the benefits conferred by this Fund take the shapes in which they are most serviceable to those in whose interest they are bestowed. It is again our privilege to make public acknowledgment of the generous services rendered to this charity by the distinguished men who have associated themselves with it in the capacities of almoners and auditor. We refer, of course, to Sir Samuel Wilks, late President, and to Dr. W. S. Church, the President of the Royal College of Physicians of London, Sir William MacCormac, President of the Royal College of Surgeons of England; Sir William Turner, President of the General Medical Council, and Sir Henry Pitman for many years associated with the first named body as its registrar. The absence of Sir William MacCormac's name from among the signatures appended to the report reminds us that his presence at the seat of the war in South Africa is a fine example of practical [illegible] which the nation will not be slow to appreciate [illegible] the [illegible] of

Sir Henry Pitman's name less suggestive, who in the fulness of many years brings a mind still vigorous in age and most notable alertness to bear upon the examination of the accounts. In presenting to each and all of them our thanks we assume to speak not only for ourselves as donors of the Fund, to whom its due administration is naturally a matter of solicitude, but in the name also of those who benefit by it and whose gratitude, not always articulate,-is in not a few cases evidenced by expressions which it is a privilege to acknowledge but a satisfaction largely alloyed with sympathetic sorrow to receive. The application form of THE LANCET Relief Fund will be found in our present issue and can be readily detached for use in case of need. We again take an opportunity of asking those of our readers who may have occasion to assist in furthering any application made for relief from this source to note carefully the conditions on which applicants become entitled to participate in the benefits of the Fund, as it is still found that many requests are put forward which are so far outside the objects of the benefaction that they cannot be entertained and from such applications nothing but disappointment can result. All applications should be made (in writing) to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London.

A MATTER FOR THE MEDICAL OFFICER OF HEALTH AND OTHERS.

MR. FRANCIS E. COLENSO writing to the *Times* under date Dec. 29th with regard to the incarceration of some natives of South Africa at Olympia says that owing to the outcry against certain natives employed at Earl's Court in the performances during the exhibition which was held there last summer the management at Olympia met the situation by simply shutting up the Zulus "within the walls of Olympia, where, except when performing, they spent their days in the twilight of a single large room, being about 50 in number with two women and a little girl." The letter really deals with the question of restricting the liberty of the Zulus, which does not come within our province, but the quotation from the letter which we have given would seem to indicate the existence of a state of things into which inquiry ought to be made. If the facts are as stated the incarceration not only constitutes a violation of the law, but forms a real danger to public health.

ANTI-ALCOHOLIC SERUM.

THE Paris Academy of Medicine at its meeting of Dec. 26th listened to a very interesting paper communicated by MM. Broca, Sapelier, and Thibaut on the discovery of a so-called anti-alcoholic serum which has already created a great deal of excitement in the daily papers and which looks rather like a trade advertisement. The three observers in question started from the principle that in alcoholic intoxication, as in morphia intoxication, there is a preliminary period which is characterised by gradual toleration of the drug and a feeling of desire for the poison. On the other hand, it is well known that certain organic poisons, more especially those produced by microbes, form in the organism antitoxins which represent the elements of resistance which the organism offers to infection. These antitoxins injected into another organism place that organism in a state of being able to resist the corresponding poison. The observers therefore determined to make research on these principles into the action of alcohol. They produced tolerance to alcohol in the horse by giving it by the mouth and then found that the serum of this horse injected into other animals which had been made tolerant and fond of alcohol produced in the animals in question such a distaste to alcohol that they preferred to give up both eating and drinking rather than continue to take alcohol. The injection of this serum in large doses has produced neither in animals nor man any unpleasant symptoms either local or general. M. Broca and his colleagues proposed to call this substance "antiethyline." Clinical experiments made upon drunkards had given most interesting and somewhat inconceivable results. The drunkard treated with antiethyline lost all his taste for alcohol; he no longer cared for brandy, rum, or absinthe, but he preserved a liking for wine and his appetite and strength returned. Up to the present antiethyline seems powerless to make any improvement in the organic alterations produced by the action of alcohol. It is only right to say that this thirsting serum which does away with any hungering after brandy but preserves the taste for wine was received by the Academy with smiling incredulity.

SEATS FOR SHOP ASSISTANTS.

WITH the first day of the new year the Seats for Shop Assistants Act came into force and with it we hope the amelioration of much suffering among a certain class of women. We say "amelioration" because the evil that has been wrought by compelling women to stand all day long in shops through ignorance and prejudice must still take time before it can be eradicated altogether. It is with particular pleasure that we announce the coming into operation of this Act because we have for years pointed out the evils of long standing in shops, more especially in regard to drapery establishments. The new Act, which is practically part of the Shop Hours Acts, is wide in its application as will be seen from the following clause:—

"In all rooms of a shop or other premises where goods are actually retailed to the public, and where female assistants are employed for the retailing of goods to the public, the employer carrying on business in such premises shall provide seats behind the counter or in such other position as may be suitable for the purpose, and such seats shall be in the proportion of not less than one seat to every three female assistants employed in each room."

The first offence of non-compliance with the provisions of the Act carries with it on conviction a penalty not exceeding £3, and subsequent offences a penalty not exceeding £5, with a minimum of £1. The new Act will be welcomed by the hard-working girls of our shops, and inasmuch as the evils from which the girls suffered frequently extended into family life the community at large is to be congratulated.

THE DISSEMINATION OF ANTHRAX.

THERE is good reason to hope that the number of cases of anthrax will, in the near future, be considerably diminished. Horsehair imported from China and some parts of Russia has long been suspected of being a source from which anthrax spores are introduced into this country, and this is now known to be the case. It would indeed be difficult to believe that those who direct the operations of the horsehair trade here were indifferent to the danger to which they, in common with their employés, are frequently subjected. The public will be interested to know that results which individual efforts on the part of manufacturers have hitherto been unable to effect are likely to be secured by the combined action which has now been organised by the leading members of the trade. Systematic inquiry has confirmed previous suspicion, and on Sept. 27th, 1899, at a meeting, held in London, of the principal firms engaged, the following resolution was passed:—"That the manufacturers present hereby bind themselves from this date to buy no Russian, Siberian, or Chinese undyed mane hair until satisfactory guarantees are given by the sellers that the hair has been thoroughly disinfected." Steps were also taken to ensure as far as possible that this action should become general throughout the trade. The recent cases reported by us on Nov. 18th, 1899, which is subsequent to the date of the foregoing resolution, have been made the subject of a very thorough inquiry by Dr. T. M. Legge, medical inspector of factories, on behalf of the Home Office, whose efforts have been ably seconded by those of the manufacturers upon whose premises the cases mentioned occurred. The inquiry resulted in the discovery that a small bale of Chinese hair, purchased some time prior to the resolution of September, was impregnated with anthrax. This bale proved to be part of a consignment landed in England about April last, whilst two other cases of anthrax occurring in other districts have been traced to other bales forming part of the same consignment. The bacteriological examinations in connexion with this case were conducted by Dr. F. W. Andrewes, pathologist to St Bartholomew's Hospital. Eventually the infected bale, while still unopened, was submitted to the dry action of super-heated steam, but this was found insufficient for the purpose of complete disinfection, cultivations being afterwards made from portions taken from the interior of the bale, finally the bale was immersed in boiling water for several hours. We have frequently pointed out the necessity for disinfection either previously to shipment or immediately after unloading at the port. It is true that the danger to those using horsehair properly prepared is reduced to a minimum, as in the process termed "setting the curl" the hair is subjected in ovens to a temperature of some 500° F., which is sufficient to ensure sterility in any germs that may be present. The greatest danger to the general public lies in the transport of infected material, and it is hoped that the action now referred to will have the desirable result of reducing that danger to a minimum.

"AIDS TO THE POOR IN A RURAL PARISH."

UNDER the above title Dr. T. N. Brushfield has collected a mine of interesting information in a paper which he read before the Devonshire Association for the Advancement of Science, Literature, and Art in August 1899. Before the Reformation there was no organised system of poor relief. The monasteries and the great religious houses gave charity in the shape of food and shelter to all the needy wayfarers who asked at their gates, but, as Dr. Brushfield points out, the position of the poor in little out-of-the-way parishes was very different. Relief in their case was almost entirely due to the efforts of the parish priest, who was generally in no way too well off, and to the generosity of the wealthy land-owners. After the spoliation of the Church the State awoke to the idea that something must be done for the poor, and voluntary effort being a marked failure the first poor-rate was empowered for collection by an Act of the reign of Elizabeth. The recognised poor-law medical officer only dates from the early eighteenth century. Previously to that date a medical man was called in as occasion arose, or more commonly the local wise man or woman. At Barnstaple in 1629 Dr. Symes was engaged by the Mayor and Corporation to reside in the town and give advice to the poor at £20 per annum for two years. At Widecombe-in-the-Moor Dr. Ball received £8 for "curing of Dorothy ffrench's legg and keeping the same sound from any more costs and charges." This payment, however, seems to have been somewhat "previous" for Dr. Ball had to return £4 "because he did not p'fect and continue the cure according to his promise." The following is a delightful item: "Ockley, Surrey, 1740. Paid for 5 pills for David Worsfold's wife 00. 00. 02½." The Settlement Act, by which strangers could be removed to their own parishes, was the cause of much inhumanity and hardship. The eighteenth century, great as it was in many ways, was not remarkable for kind treatment of the poor. For instance, the registers of St. Giles, Cripplegate—it is one of life's little ironies that such proceedings should have taken place under the ægis of St. Giles—contain such entries as the following: "1725. To A. Walsham for getting a dying man out of ye Parish 0. 1. 0 To a person for getting a dieing man out of ye parish 0 0. 6." Death, of course, sometimes ensued upon these removals, as witness the following pathetic entry from the registers of Milton Abbot, Devon. "1588 Payd to Wm. Ketowe for a shroud for a poor man which dyed within this parishe which was carried from tythinge to tythinge ...... xvjd." The Poor-law is not perfect now but it has improved. We have only selected the more purely medical portions of Dr. Brushfield's interesting paper upon which to comment, but besides these it contains a vast amount of valuable information upon early poor relief which makes it well worth reading as a whole.

DEATH WHILST UNDER ETHER: ASPHYXIA FROM ŒDEMA GLOTTIDIS.

THE following case, the notes of which are kindly supplied by Miss Aldrich-Blake, M.D., M.S. Lond., presents some unusual points of interest. The patient, a woman, aged 23 years, was under treatment at the Royal Free Hospital for an abscess below the left ramus of the mandible. Her general state was poor but she had no obvious dyspnœa and no circulatory embarrassment. There were great œdema of the glottis and thickening of the tissues caused by the cervical abscess. On Dec 6th she was given ether by Miss Watts, M.B., the assistant anæsthetist to the hospital. A Clover's inhaler was used. The patient breathed quietly for four minutes, then respiration became shallow and very rapid. The face-piece was removed and not again re-applied. The "lid reflex" we are told "was brisk," but the patient was very pale. No cyanosis was present. From this moment, however, the respiration became increasingly shallow and cyanosis appeared and deepened, and finally breathing ceased. To relieve these symptoms the jaw was pushed forward and the tongue was drawn out while artificial respiration was practised. Air did not enter the lungs freely nor did the cyanosis lessen. Artificial respiration was kept up for half an hour. The heart beats were felt for some time after natural breathing had ceased. Strychnine and ether were injected hypodermically. The necropsy showed marked œdema of the glottis. In cases of angina Ludovici, abscesses, and the like causing pressure upon and inflammatory thickening around the glottis dangers associated with anæsthetics are peculiarly liable to occur. In the matter of choice of the anæsthetic we are very doubtful whether ether offers the best chance of escaping the inherent perils of the situation. It increases the fulness of the neck, promotes dyspnœa, and induces cyanosis. Certainly, if œdema glottidis is known to exist ether is not, in the view of many experts, the best agent to employ. On the other hand, it must be admitted that in the less severe cases of angina Ludovici ether can be given without greatly increasing the dyspnœa. In the present case there appears to have been no cardiac weakness, so that ether was not peremptorily called for to sustain a flagging circulation. Reverting to the best means of helping patients in such grave danger it appears difficult to understand why the obstruction to respiration, which appears from the notes before us to have been purely mechanical, was not removed by opening the trachea below the seat of obstruction. In some cases such an operation is extremely difficult if not impossible, but clearly it is the thing to do if artificial respiration fails to aerate the blood. There are other remedial measures which suggest themselves. The forcible traction on the epiglottis or base of the tongue with a tenaculum certainly opens the rima when tongue traction [illegible] forceps fails.

but, if the œdema has closed the laryngeal chink this manœuvre may fail. Intubation and forced respiration by means of bellows can be successfully employed when the external swelling and displacement of parts render a tracheotomy or laryngotomy impossible. Professor Wood contends that forced respiration is in all cases more valuable than Silvester's method of artificial respiration. In commenting upon this case we wish to be understood to make no adverse strictures upon the manner in which the hospital authorities carried out their difficult task of attempting to save the patient's life. Measures which appear obvious to those who read an account of an emergency such as has been described cannot always be adopted and only those who are actually present and who know all the circumstances of the case can decide what can be done and what cannot be done to avert threatened dangers.

THE LIVINGSTONE EXHIBITION.

THIS exhibition, opened on Jan. 1st, in St. Martin's Town Hall by the Livingstone College, was intended to instruct the public and travellers in particular in the requirements necessary to health when exploring unknown tracts of country and when residing in climates more or less unhealthy. Portable beds and other articles of furniture, clothing, foods of various kinds, and medicines suitable for travellers were shown and the collection thus brought together has no doubt proved highly useful to the missionaries and others to whom the exhibits practically appealed. On Thursday last Major R. Ross, I.M.S., gave a lecture on the Malarial Mosquito, and to-day (Friday) Miss Kingsley lectures at 3 P.M., and Dr. Harford Battersby, M.A., gives a lecture on the Preservation of Health in Tropical Climates at 5.30 P.M. An interesting feature of the Exhibition was the collection of relics of Dr. Livingstone, arranged by his son-in-law, Mr. Frank Wilson, and loaned by various people and societies. Mementoes of Mungo Park, Speke, Burton, and other explorers were also included. We need not point out the usefulness of such an exhibition as this if made a permanent one, and it is to be sincerely hoped that the Livingstone Exhibition is but the forerunner of a free public exhibition on similar lines. There should be no difficulty in bringing this about seeing that the Livingstone Exhibition is under the patronage of the Princess Christian and is supported by leading members of both the medical and clerical professions, whilst various Government Departments, the Royal Geographical Society, and the Royal Colonial Institute gave their support or expressed their approval of its objects.

METHOD OF EARLY DIFFERENTIATION OF TYPHOID FEVER.

PIORKOWSKI[1] reports at length on 40 cases in which he was able to make the diagnosis of typhoid fever from the third day of the disease to three days after the subsidence of the fever and was successful in doing so on occasions when the Widal test failed. The method consisted in making cultures from the fæces of suspected cases, and is as follows:—The nutrient medium is prepared by using a one half per cent. solution of peptone with 3.3 per cent. solution of gelatin. To this mixture is added a small quantity of normal urine which has been kept for a few days at the ordinary temperature of the room until it has become slightly alkaline. The three-fold mixture is now filtered and sterilised in test tubes for 15 minutes at a time on two successive days. The medium thus prepared can be spread on sterilised glass plates and cooled by ice until solidified. Loop cultures from the fæces are made on the plates thus prepared and the plates thus inoculated are transferred to a thermostat and temperature of from 21.5° to 22° C. In from 15 to hours colonies of the typhoid bacilli appear in oblong groups, the margins of which gradually becom round as the colony enlarges. They now appear of yellowish colour, finely granular, and surrounded by delicate characteristic tangle of filaments set out in spira form in the gelatin. (The colonies of the bacillus col communis are sharp-edged, coarsely granular, darker i colour, and larger than the above.) It is important note that these results are confirmed by other observer Thus Schütze confirms Piorkowski's views with hi experience of six cases, and states that the method is o "remarkable, even decisive importance in establishing positive diagnosis in the early stage of typhoid fever." Unger reports 12 cases thus diagnosed, but records tw others in which the technique failed because the urine wa too intensely alkaline. H. Wittich after putting the proces to a careful test[2] confirms the results reached by Piorkowski He supplements, however, the original observations of the latter by pointing out that the colon bacillus grown on this medium may occasionally simulate the appearance of the typhoid culture colonies rather closely. In this case the former can be distinguished by the pink colour, the faint indol reaction, the curdling of milk, and the production of gas with a ¼ to ½ per cent. grape-sugar bouillon.

"THE MEDICAL SERVICE OF THE HEBRIDES."

WE are glad to know that our leading article on this subject has received a considerable amount of attention. Mr. H. Smith, burgh sanitary inspector, and Dr. C. M. Macrae, medical officer of health of Stornoway, in a letter to the editor of the *Highland News*, object to the suggestion that Lewis is a home of typhus fever and, with the other islands of the Hebrides, a source of risk to large towns. The general drift of our article on the medical service of the Hebrides was to point out the inadequacy of the medical service, the need for more isolation hospitals and for more nursing in dealing with infectious disease. We adhere to our statement that Lewis is a home of typhus. Dr. Bruce says in his report for 1898 that "typhus still lingers in Lewis." On page 9 of his report he says: "With regard to hospitals I repeat that such are absolutely essential where the living houses are so bad. To be properly treated the patients must be removed from the polluted atmosphere reeking in germs to the clean pure air of a small properly warmed and well-ventilated infirmary. As has been pointed out to me by our most distinguished living sanitarian, such removal is needed more even for the safety of the nurse than for the care of the patient." He adds: "In typhus this is a serious danger, as was proved lately not very far from ourselves." In the same report he quotes Mr. R. Ross's report on the parish of Barvas: "Two cases of typhus occurred at Borve in April and other two at South Bragor in June. There was one case each of typhoid, puerperal fever, and erysipelas, and *seven cases of continued fever*. There were two cases of diphtheria and four of scarlatina." The italics are ours. Dr. Macrae and the sanitary inspector boast in their letter, and no doubt too truly, of the familiarity of the medical men of the island with fever varieties. Yet here are seven cases of fever undefined, of which it is not uncharitable to suppose that several, if not all, were mild cases of typhus. Dr. Bruce at any rate will not quarrel with us for regarding Lewis as a home of typhus fever or in thinking that the mere use of disinfectants will do little to abate the insanitary condition of the island and the neighbouring islands, while such home conditions exist as are indicated in his reports and those of Dr. O. Grant, the medical officer of health of

---

[1] Deutsche Medicinische Wochenschrift, Nov. 16th, 1899

[2] Centralblatt für Bakteriologie und Parasitenkunde, Oct. 28th, 1899.

Inverness-shire. Dr. Grant, at page 32 of his report for 1898, quotes Mr. D. Fletcher, parochial medical officer of North Harris, to the following effect: "I regret to find that, in spite of all pressure brought to bear on the cattle housing system, there are still some in North Harris who stick with dogged persistency to the traditions of their fathers and keep their cattle under the same roof as themselves. There is room for much improvement in the housing of the people generally, the old mud wall being still the rule. One need hardly expect to stamp out typhus when such suitable media for the preservation of its germs exist."

MICROBES IN HOLY WATER.

OUR Rome correspondent, in his letter which appeared in THE LANCET of Dec. 23rd, 1899 (p. 1782), made the suggestion that the salt which from the earliest ages has been mingled with the water used for ceremonial purposes should be modified so as to make it a true disinfectant. Salt as the best known and probably the earliest used substance for preventing decay was most likely added originally purely from its symbolic meaning, though possibly the symbolism, as in so many other instances, grew side by side with the literal meaning. According to the *Catholic Times*, of Dec 29th, 1899, the *Osservatore Romano* does not fall in with our correspondent's suggestion, avowing that, the water being holy, needs no human treatment and has never hitherto been regarded as a channel of disease. The *Catholic Times* goes on in the following eminently sensible fashion, "God has given us intelligence for use and even when He blesses requires us to take the ordinary precautions which reason suggests. The argument that no change is advisable because the necessity for it has not been suspected before now cuts at the ground of improvement." We are glad to be able to note these remarks of our contemporary as showing the accordance of common sense lay opinion with that of scientific men. We have previously pointed out[1] how the Church has always taken cognisance of men's bodies as well as of their souls. There must be no standing still in either religion or science, for in both the intellect is striving to reach heights at present beyond it, but which shall one day be attained, and that which is now dark shall be made light.

KERNIG'S SIGN IN MENINGEAL HÆMORRHAGE.

IN 1884 Kernig described a phenomenon which he thought was found only in affections of the pia mater and always in inflammations of it. When the patient is recumbent the legs can be easily extended on the thighs, but when he sits up extension is rendered impossible by contracture of the flexor muscles. After having attracted but little notice during 14 years Kernig's sign has recently received considerable attention and has been found to be of great value in the diagnosis of meningeal diseases. In the main Kernig's conclusions have been confirmed; the sign appears to be present in about from 60 to 90 per cent. of cases of meningitis. At the meeting of the Société Médicale des Hôpitaux on Dec. 1st, 1899, MM. Fernand Widal and Prosper Merklen called attention to the occurrence of Kernig's sign in cases of meningeal hæmorrhage and to its *diagnostic* value. Cases of meningeal hæmorrhage in which the sign has been observed are rare, though such have been recorded by Kernig himself. MM. Widal and Merklen related the case of a healthy man, aged 32 years, who while writing in his office without any premonitory symptoms fell from his chair unconscious. He regained consciousness in some hours without having shown any change in temperature, paralysis, or contracture. He complained only of intense headache affecting the whole head and then of pain in the back. Movements of the trunk were difficult and painful. The pupils were slightly dilated, the eyes were suffused with tears, and the face was congested. There was neither albuminuria nor glycosuria. When the patient was recumbent the legs were extended on the thighs, but when he sat on the edge of the bed the legs became flexed in contracture and could not be extended. He remained in this state for four days On the fifth day the temperature rose to 100 4° F. and there was slight contracture of the neck; on the sixth and seventh days the temperature oscillated between 100 4° and 101 8°. Kernig's sign persisted and the headache and backache were intense. On the ninth day death occurred suddenly from syncope. At the necropsy a clot was found beneath the arachnoid membrane extending as far forward as the optic nerves; it was prolonged on the anterior surface of the pons, medulla, and cord as far as could be seen through the foramen magnum. The spinal canal was full of liquid blood. The posterior and superior region of the cord was congested. The posterior spinal artery was dilated and was full of little disseminated clots. This was the only lesion of the central nervous system found after the most minute examination. The mechanism of the meningeal hæmorrhage escaped observation Probably syphilis (which the patient had contracted seven years previously) played a part. In this case but for Kernig's sign a meningeal lesion would not have been suspected No doubt irritation of the meninges by the clot is the cause of the phenomenon.

DERMOID CYST OF THE OVARY WITH TWISTED PEDICLE IN A CHILD.

IN the *Boston Medical and Surgical Journal* of Sept. 28th Dr. J. V. Meigs has published a case of this rare condition which is further interesting in consequence of urinary symptoms which caused difficulty of diagnosis from hydronephrosis. A female child, aged 10 years, was healthy except for occasional painful micturition with incontinence or suppression of urine While playing she fell from a swing on the buttocks Immediately intense abdominal pain supervened, which increased. On undressing the child the mother noticed for the first time a swelling in the abdomen The patient was sent to a hospital, where distended bladder was *diagnosed*, but *on* catheterism only about an ounce of urine was obtained. The abdomen was very tender and somewhat tympanitic, and examination was possible only under an anæsthetic. The child was beginning to show evidence of shock. Hydronephrosis caused probably by a kink or twist of the ureter from the fall was diagnosed. When the patient was anæsthetised a *somewhat* solid tumour as large as a cocoanut and moveable was found below and to the right of the umbilicus. Laparotomy showed a dermoid cyst of the right ovary with the pedicle twisted one and a half times. The cyst was dark from impairment of the circulation. It was removed and found to contain sebaceous matter, cartilage, and bone. Recovery ensued

CELLAR DWELLINGS IN STOCKPORT.

DR. CHARLES PORTER, the medical officer of health, recently submitted to the Sanitary Committee of the Town Council of Stockport a report upon cellar dwellings. On Nov. 3rd, 1899, Mr. Justice Bucknill made some remarks upon certain evidence which was given and inquired if there were no law in Stockport that people should not live in these cellars. A Manchester paper further stated that some of these dwellings were "practically of modern construction" Dr. Porter points out that in the opinion of the borough surveyor no cellar dwelling has been erected since 1875 owing to the Public Health Act of that year prohibiting their erection. As to Mr. Justice Bucknill's question there is no law in Stockport or anywhere else to prevent people living in a cellar because it is not so clean as it might be (which was the only evidence given before the court as to the cellar in question). The Public Health Act of 1875, however, lays down certain requirements for cellar dwellings. Dr. Porter, in mentioning that there are still 157 cellar dwellings in Stockport, states that they have been periodically visited and inspected with regard to the requirements of the Act. Most of them are nominally deficient in one respect or another, 68 have no drain, and 57 are without any means of through ventilation. Dr. Porter points out that many of these dwellings are kept scrupulously clean and afford a last asylum to "scores of poor worn-out old souls." He therefore thinks that the strict letter of the law should not be enforced but that the cellar should only be closed when the tenant leaves. He concludes his report by asking if it be not possible as an ordinary commercial speculation to provide dwellings in which deserving old people could get a healthy room for 1*s.* per week. We are glad to see that the Sanitary Committee are not going to alter their mode of procedure so that the aged tenants will be undisturbed until they "leave." Cellar dwellings are not desirable but there are occasions in which mercy is better than sacrifice.

[1] THE LANCET, Sept 18th, 1897, p 733.

CHARITABLE BEQUESTS AND DONATIONS IN 1899.

IN summarising the bequests left to hospitals and medical charities during the past year the *Charity Record and Hospital Times* says that £1,390,136, as against £1,303,720 in 1898, have gone to medical charities. Referring to donations our contemporary remarks that it is impossible to make any comparison. "Up to the commencement of the war large donations were fairly frequent, but in the last few months they have been more conspicuous by their absence." Early in the year the executors of Mr. F. C. Baines gave £10,000 to the National Lifeboat Institution, and Mr. W. Cadge gave £10,000 to the endowment fund of the Norfolk and Norwich Hospital, while Mr. J. Wheeler Bennett, as a New Year's gift, presented the Bromley (Kent) Cottage Hospital with £4,000. Mr. J. Robinson undertook to build a new wing to the Nottingham Hospital. Mr. E. P. Wills gave £25,000 to the Bristol Jubilee Convalescent Home. "Mr. A. H. Moncur has offered to build a Sanatorium for Consumption at Dundee at a cost of £10,000, and an anonymous donor offered £5000 for five years if the scheme were carried out, and both offers have been accepted. The anonymous donor 'M.' has given another £5000 to Guy's Hospital. The Earl of Leicester has given another £5000 to the Norfolk and Norwich Hospital, thus raising his total gifts to this institution to £40,000. With a view to enabling the committee of the Newcastle-on-Tyne Infirmary to claim a large legacy Mr. J. Eno gave £8500. The Duke of Westminster presented the Eclipse Stakes of £10,000 to the Royal Alexandra Hospital, Rhyl. Mrs. T. Lund has offered £5000 to establish almshouses at Pudsey and Lord Ashton has handed a cheque for £10,000 to the secretary of the Royal Albert Asylum for Idiots, Lancashire."

WE beg to call the attention of our readers to the letter signed by Dr. Frederick Roberts, Mr. Edmund Owen, Dr. W. Collingridge, Dr. W. Duncan, and Dr. J. E. Squire, appealing to the younger members of the profession to enrol themselves in the Militia, Yeomanry, and Volunteer forces. In the face of present circumstances it becomes the duty of every man to bear any part that he can in our Imperial defences, and we feel sure that the medical profession will not be slow to respond to the appeal of Dr. Roberts and his co-signatories.

AN HISTORICAL RECORD OF THE USE OF PRESERVATIVES AND COLOURING MATTERS IN FOOD,

ACCORDING TO THE INQUIRIES OF THE ANALYTICAL SANITARY COMMISSION OF THE LANCET FROM 1851 TO THE PRESENT TIME.

AS is well known, the question of colouring matters and preservatives in food is receiving the earnest attention of a committee of inquiry appointed some months ago by the Local Government Board. Already a considerable amount of valuable evidence has been given which in view of its importance and of its great public interest we have published and shall continue to publish at length in our columns. We may claim fairly, we think, to have adopted an initiative inquiry upon the subject in its modern aspect ourselves three years ago when we invited certain recognised authorities on food and drugs to give us their opinions, which we subsequently published, together with the results of our own work, in THE LANCET of Jan. 2nd, 1897, page 56, under the heading of THE LANCET Special Sanitary Commission on the Use of Antiseptics in Food. These opinions were summarised by our own Commissioners and we believe that this contribution on the subject has been of material service to the Preservatives Committee. The purpose of the present article is to show that the subject has an interesting history dating back, so far as the work of THE LANCET is concerned, nearly half a century.

Undoubtedly attention was first drawn to the preservation and artificial colouring of food with the commencement of the labours of the Analytical Sanitary Commission of THE LANCET which was instituted in the year 1851 by the late Mr. Thomas Wakley, M.P., the Founder of the journal. The gross forms of fraud which this Commission brought to view were in the main not related to the specific subject which the present Committee on Preservatives are considering. Nevertheless some important matters were touched upon which bear distinctly upon the history of the employment of preservatives and colouring matters in food, and which, therefore, we venture to think are of special interest at the present time.

The first report dealing with the adulterations of coffee contains little that is germane to the subject, but in THE LANCET of Sept. 20th, 1851, page 279,

THE ADULTERATIONS OF MILK

are described. In this article mention is made of the use of turmeric added for the purpose of producing in milk a richness of colour, making the dilution with water and abstraction of cream less apparent. In the same article reference is made to the addition of carbonate of soda to prevent milk from turning sour. Milk thus treated may be kept, it is said, for eight or ten days. Again, milk of almonds is referred to as being sometimes present in milk, and as oil of almonds is decidedly antiseptic, the object of its addition was probably for preserving purposes or as a corrective. This seems to be the first historic reference to the use of preservatives in milk.

The next reference to the use of a preservative was in connexion with the

ADDITION OF SULPHURIC ACID TO VINEGAR.

THE LANCET Commission[1] regarded this addition as unnecessary, since some makers dispensed with it altogether. As a result of the inquiry it was shown that of 33 samples analysed eight samples contained a quantity of sulphuric acid not exceeding the amount permitted to be added, while in the remaining cases the amount exceeded this, and in some instances was three or four times as great.

The next inquiry (1852) related to

PICKLES

and their adulteration, and here again the presence of free sulphuric acid was shown and of copper in varying amounts in the samples purchased In two instances the amounts were poisonous The pickles which contained the largest quantity of copper were those which consisted entirely of green vegetables as gherkins and beans "One of the worst features of this abominable practice,' remark The Lancet Commission, " is that the employment of copper is wholly unnecessary, as the colour of green vegetables may be very well preserved by other means, as by the use of pure vinegar and the addition of a proper quantity of salt "

---

[1] THE LANCET, Jan. 10th, 1852, p. 51

The next important article dealt with

PRESERVED PROVISIONS

and appeared in The Lancet of March 20th, 1852 In this article reference is made to the means of preserving various foods but the only preservatives mentioned are salt sugar, oil, charcoal, acetic acid, pyroligneous acid, and alcohol A number of samples were examined including carrots, turnips peas, rhubarb cabbage, Brussels sprouts, potatoes, apples, extract of beef, soups, fish, and beef pemmican Out of the 34 samples of preserved provisions of all kinds submitted to examination the condition of preservation of 29 was most satisfactory, the state of five only out of the number being unsatisfactory, three of these being vegetables It was concluded on the whole that the several processes adopted for the preservation of vegetable and animal substances so far as regards home and domestic use were productive of satisfactory results From the few cases, however, which had turned out unfavourably it was evident that the greatest care was requisite in conducting the several steps of whatever process was adopted

The next report was devoted to the examination of

CAYENNE PEPPER

purchased at the establishments of grocers and oilmen resident in the metropolis and the results were startling Cinnabar, vermilion or sulphide of mercury was detected in one sample Six of the samples consisted of a mixture of ground rice turmeric, and cayenne coloured with either red lead or a red ferruginous earth Venetian red red ochre, and brick dust occurred in seven samples red lead in poisonous quantities in 13 samples, while of the 28 examined 22 contained mineral colouring matter Practically the same substances and colouring agents were found in

CURRIE POWDER

the report including the analysis of 26 samples, appearing in The Lancet of July 17th 1852

The next Commission dealt with

PRESERVED BOTTLED FRUITS AND VEGETABLES

Twenty seven samples out of 33 contained varying quantities of copper This was true for gooseberries, rhubarb and greengages, but not for red fruits like currants raspberries and cherries Several specimens of green fruits and vegetables were free from copper Olives contained a very large amount of copper The colour of green fruit and vegetables was the Commission remarked, apparently heightened by a second device, the bottles in which they were enclosed were made of a highly coloured glass, those in which French olives were preserved were of so intense a green as to impart to the fruit a deep green colour even without the aid of copper

The next inquiry of interest to the Committee related to

ANCHOVIES,

in which red lead was occasionally found In 23 out of 28 samples bole Armenian or Venetian red was found Much the same class of colouring material was found in many samples of potted meats and fish the report appearing in The Lancet of Nov 13th 1852

The next inquiry related to

SAUCES,

in which apparently in some instances charred deal wood was used for imparting colour Cochineal and bole Armenian were found in essence of lobster, shrimps, and anchovies

An interesting letter appeared in The Lancet of Jan 15th 1853 from the late Dr Bernays lecturer on chemistry at that time in St Thomas's Hospital Referring to the work of The Lancet Analytical Sanitary Commission Dr Bernays noticed that when eating

GOOSEBERRIES

with a steel fork the prongs became completely coated with a thin film of bright metallic copper

PRESERVES AND JELLIES

were next the subject of inquiry the results being recorded in The Lancet of Jan 22nd 1853 Some 35 samples were examined Raspberry jam, gooseberry jam, greengage jam, the greengages of crystallised fruit limes and green gages, and candied citron peel, all owed their brilliant colour to a salt of copper

The next subject forming the basis of a report was

LARD,

where the chief form of adulteration appeared to be caustic lime " to improve consistence and colour

Later, in The Lancet of June 4th 1853, it was shown that

BUTTER

was heavily preserved with an excess of salt, but no other preservative was mentioned

A pause appears to have occurred at this date in the work of the Commission the next article appearing in The Lancet of Dec 3rd, 1853 which related to the analyses of 43 samples of

SNUFF

In many instances red ochre, yellow ochre and umber were found as colouring agents Chromate of lead, oxide of lead, and bichromate of potash were found in other samples

In the following year, in the issue of The Lancet of May 27th 1854, appeared a remarkable report on the

COLOUR USED IN CONFECTIONERY

Yellow sweets were found coloured with chromate of lead and gamboge red sweets were coloured with red lead, vermilion or sulphide of mercury, brown sweets were coloured with umber and sienna, purple sweets with Prussian blue and cochineal, blue sweets with indigo, Prussian blue and ultramarine, green sweets with Brunswick green, a mixture of chromate of lead and Prussian blue, and others were coloured with carbonate of copper and Scheele's green or arsenite of copper In cake ornaments white lead was frequently found In this report several instances are given of poisoning by the consumption of articles so coloured

With this terrible indictment the work of the Commission, as it relates to the subject of inquiry before the Committee on Preservatives, ceased until seven years later In 1861 and 1865 The Lancet Analytical Commission resumed its inquiry and on these occasions devoted its attention again to

PRESERVED PROVISIONS

in which it was shown that copper was still employed to a very large extent in green preserved fruits and vegetables, although the samples obtained from big firms which are still well known were shown to be free from copper Also it was shown that the gross forms of adulteration of

CAYENNE,

as with lead and mercury, had to a large extent subsided At the same time it was also shown that

MUSTARD

was less adulterated and that turmeric as a colouring agent was the exception rather than the rule There is a vast amount of further information in these reports bearing on the general adulteration of food up to that time It would clearly appear that up to this date the present methods of preserving and colouring foods were unknown That attempts were, however, very strenuously made to institute a satisfactory method for the preservation of food is abundantly clear from a perusal of The Lancet from 1854 to 1896 Editorial articles appeared again and again as to the merit of certain processes, and analyses were quoted clearly emanating from The Lancet Analytical Sanitary Commission dealing with the products of these methods It is interesting to quote one article which appeared in The Lancet of Jan 19th, 1867

In this article the efforts that had been made towards

PRESERVING ANIMAL FOOD SUPPLIES

were described Omitting to mention the methods of tinning meats in vacuo we refer for the purposes of the present inquiry to the section of this article which deals with antiseptics It would appear that sulphurous acid and the sulphites were tried, with the result that though to some extent the meat was preserved from putrefaction, yet the flavour of the meat so treated put the method out of court The use of nitric oxide was also suggested In summing up The Lancet writes ' It may be safely asserted that no method is known to science by which the decomposition of raw meat can be prevented especially in tropical climates without the employment of [illegible] which in order to accomplish the [illegible] of the meat and its juices. It may also be safely asserted that there are no known antiseptics capable of producing the required effect that would not either destroy the nutritive properties of the meat or communicate to it a decided flavour that would interfere with its use as a food. Salt is the only chemical agent that has been used with any good effect, but something better than salt meat is wanted." Here, again, there is no mention of the use of modern antiseptics such as borax or salicylic acid.

Apparently the first mention of a modern preservative in milk was in THE LANCET of Jan. 20th, 1877. The preservative was salicylic acid. Next in the issue of Jan. 11th, 1879, borax is mentioned as being used in meat. It is curious to note that the employment of modern antiseptics for the preservation of food was introduced much about the time which Lord Lister introduced his method of antiseptic treatment. Lord (then Mr.) Lister's discovery was announced in 1870, and in the following years the Listerian methods were adopted, with what remarkable results in the history of medicine every medical man knows.

In THE LANCET of April 10th, 1886, page 700, an editorial note appeared on the

INCREASING USE OF PRESERVATIVES IN FOOD.

Benzoate of soda appears then to have been regarded as the best agent. Boric acid is described as undesirable and injurious especially when present in milk for infant use. In another article which appeared on page 1142, Vol. ii., 1886, the results of the examination of

BORATED FISH

are reported. Here it is stated that apparently boric acid is not truly a preservative, and that blackening of the flesh was noticeable.

In several articles which appeared in the second volume of THE LANCET of 1887, the increasing use of

BORIC ACID IN MILK

was pointed out and appeal was made for attention to the subject. One of these articles was the translation of Dr. Forster's report in *Dingler's Polytechnisches Journal*, 1884, page 170, on the use of boric acid as a so-called food preservative. This will be found to be a very interesting physiological inquiry, which would appear to have anticipated modern experiments. The result was distinctly unfavourable to the use of boric acid. The publication of this article in the columns of THE LANCET led to what must be regarded as the first public agitation on the subject. It received considerable comment at the hands of the public analysts, which culminated in the

FIRST CASE OF PROSECUTION

instituted under the Sale of Food Acts. The case failed on the point of an added and, as it was urged, injurious preservative, but succeeded on the point of abstraction of fat.

In a leading article in THE LANCET of Jan. 10th, 1891, in commenting upon this case THE LANCET remarked that the "question is an important one, and calls for immediate investigation, and the consensus of medical opinion must be gained." This is exactly the present position and a position which the Committee are appointed to elucidate. As to the evidence of the use of preservatives and colouring matters in food following the date of this remark (Jan. 10th, 1891) up to the present time particulars have already been furnished to the Committee by medical men, public analysts, and others.

THE LANCET Laboratory.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THE following is a list of the grants recommended by the Distribution Committee:—

Alexandra Hospital—Donation, £500. Belgrave Hospital—Donation, £500 (to help the hospital to remove to the South of London). Bolingbroke Hospital—Donation, £1000 (towards the rebuilding). British Lying-in Hospital—Donation, £100. Cancer Hospital (the committee consider this to be a well-managed hospital but not in need of a grant this year). Central London Ophthalmic Hospital—Donation, £100 (towards the rebuilding). Central London Throat and Ear Hospital—Donation £150 (towards an operating room). Charing-cross Hospital—Annual, £1000 (in the hope that the improvements required will be put in hand forthwith). Chelsea Hospital for Women—Donation, £250. Cheyne Hospital—Donation, £100 (in consideration of the fact that curable cases are admitted). City of London Chest Hospital—Annual, £1500 (grant is increased by £500 to enable the re-opening of another ward of 10 beds). City Orthopædic Hospital—Annual, £250 (the amount named by the authorities as required to open the remaining 20 closed beds). Clapham Maternity Hospital—Donation, £250 (towards the building fund). Cottage Hospital, Canning Town—Donation, £100 (towards the building fund). Dental Hospital—Donation, £100. "Dreadnought" Hospital—Annual, £500; donation, £200 (£500 annual as before, £200 for the Tropical Diseases Department). East-End Mothers' Home (the income of this institution appears this year to be sufficient). East London Hospital—Donation, £250. Establishment for Gentlewomen—Donation, £75. Evelina Hospital (no grant is recommended as the income appears to be sufficient this year). French Hospital—Donation, £100. Gordon Fistula Hospital—Donation, £100 (towards furnishing). Great Northern Central Hospital—Annual, £750 (as before). Grosvenor Hospital—Donation, £100. Guy's Hospital—Annual, £5000. Hampstead Hospital—Donation, £100 (towards the salary of a house surgeon). Hospital and Home for Incurables, Maida Vale (an institution for incurables only). Hospital for Diseases of the Throat (their claim to be considered another year when their building is completed). Hospital for Epilepsy and Paralysis—Donation, £250 (for rebuilding). Hospital for Sick Children—Annual, £500. Hospital for Women, Soho-square—Donation, £350. Hospital of St. John and St. Elizabeth (no grant is recommended this year. Their case to be considered after the building is opened). Infirmary for Consumption (not considered to be within the scope of this fund as a hospital). Italian Hospital—Donation, £100 (towards furnishing the new building). King's College Hospital—Annual, £1000; donation, £175 (£1000 annual, £175 towards out-patients' department). London Fever Hospital—Donation, £200 (attention to be drawn to the necessity for certain reconstructions). London Homœopathic Hospital—Donation, £200. London Hospital—Annual, £5000. London Lock Hospital—Donation, £500. London Temperance Hospital—Donation, £600. Memorial Cottage Hospital—Donation, £50. Metropolitan Hospital—Donation, £1000 (committee trust that the efforts of the authorities will be continued successfully and the debt paid off with the assistance and encouragement shown in this increased grant). Middlesex Hospital—Annual, £1000 (as before). Mildmay Mission Hospital, Donation, £250. Miller Hospital—Donation, £300. National Hospital for Paralysed—Annual, £750. National Orthopædic Hospital—Donation, £100. New Hospital for Women—Donation, £100 (towards the purposes named by the visitors). North-Eastern Hospital for Children—Annual, £500; donation, £250 (£500 annual, £250 towards building). North London Hospital for Consumption—Annual, £1000. North-West London Hospital—Donation, £500. Paddington-green Hospital—Donation, £150. Poplar Hospital (an admirably conducted institution, but does not seem to require help this year). Queen Charlotte's Hospital—Donation £300. Queen's Jubilee Hospital (this institution does not appear to be a hospital in any true sense of the word, and its buildings are quite unsuitable for hospital purposes). Royal Ear Hospital (their claim to be considered when the removal is completed). Royal Eye Hospital—Donation, £100. Royal Free Hospital—Annual, £750; donation, £500 (of which £750 is annual, and £500 a donation towards improving the accommodation for nurses). Royal Hospital for Women and Children—Donation, £100 (the committee desire to draw attention to the need for rebuilding). Royal Hospital for Diseases of the Chest, City-road—Donation, £250 (towards improving the nurses' accommodation). Royal London Ophthalmic Hospital—Donation £750. Royal Orthopædic Hospital—Donation, £250 (towards the expense of rebuilding the hospital on a new site). Royal Westminster Ophthalmic Hospital (no grant this year). Samaritan Free Hospital—Annual £500. St. George's Hospital (although in view of the financial position of the hospital the committee are unable to recommend a grant, they cannot but express their unqualified approbation of the excellent work that has been done in the way of improving the nursing accommodation and reconstructing the theatre). St. Mark's Hospital (the committee consider that the financial position does not seem to require help this year). St. Mary's Children's Hospital, Plaistow—Donation, £500 (£200 for maintenance, £300 towards the improvements named by the visitors). St. Mary's Hospital, Paddington—Annual, £1000. St. Monica's Hospital—Donation, £50 (the committee desire to draw attention to the fact that there is no isolation ward). St. Peter's Hospital for Stone—Donation, £50. St. Saviour's Hospital—Donation, £50. St. Thomas's Hospital—Annual, £1800 (the committee consider that an inquiry officer is needed to prevent abuse by out-patients). Tottenham Hospital—Annual, £1000; donation, £500 (£1000 of this is annual towards the opening of one closed ward containing about 15 beds; £500 donation). University College Hospital—Annual, £1400 (as before). Victoria Hospital for Sick Children—Donation, £500 (towards the new building. The committee recommend, in view of the fact that the new building is to cover all the available garden space belonging to the hospital, that a flat roof should be made on the new building for air and exercise). West-End Hospital for Diseases of the Nervous System—Donation, £100 (towards a new operating room). Western Ophthalmic Hospital—Donation, £50. West Ham Hospital—Annual, £300; donation, £250 (£300 annual grant, £250 towards repairs and alterations necessary). West London Hospital—Donation, £1000 (the authorities having agreed to carry out the recommendations of the visitors). Westminster Hospital—Annual, £750; donation, £250 (£750 annual, £250 towards the cost of nurses' quarters). Wimbledon Hospital—Donation, £50.

Total annual grants, £26,250; total donations, £14,750.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Hospital Saturday, recently held in Plymouth, has resulted in the sum of £601 being raised for the funds of this institution. The Sunday Schools Collection, in aid of the Children's Ward, realised £64.

PAUPERISM IN THE CHARD UNION.—Mr. Preston Thomas, the Local Government Board inspector for the south-western counties, has drawn the attention of the Chard Board of Guardians to the fact that the rate of pauperism in their union is no less than 44 per 1000, whereas the rate throughout England and Wales is only 26 per 1000.

THE LANCET RELIEF FUND.

ELEVENTH ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians of London (Sir SAMUEL WILKS, Bart., F.R.S., during the first three months of last year and subsequently Dr. WILLIAM SELBY CHURCH), the President of the Royal College of Surgeons of England (Sir WILLIAM MAC CORMAC, Bart., K.C.V.O.), the President of the General Medical Council (Sir WILLIAM TURNER, M.B. Lond., F.R.C.S. Eng. and Edin., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the eleventh annual report the Almoners think it well again to direct attention to the object for which the Fund was established.

The Fund is sustained solely by the Proprietors of THE LANCET who provide every January the sum of at least £300 and is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners or to the widows and orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and as a result the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—and who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1898 amounted to the sum of £318 5*s.* 8*d.* On Jan. 2nd, 1899, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. The sum of £255 has been granted in relief either by way of loan or of gift, leaving a balance of £358 1*s.* 6*d.* as per Statement of Accounts.

There have been considered altogether during the 12 months ending Dec. 31st, 1899, 33 applications for relief (the number the previous year having also been 33). In 24 cases assistance was awarded either as a loan or as a gift according to the request of the applicant, the amounts of the grants ranging this year from £5 to £20.

The Almoners are glad to find from the number of letters received from recipients of the Fund that it continues to be of service to unfortunate members of the profession and that the particular object of assisting cases of emergency and immediate distress has been attained.

(Signed),

WILLIAM TURNER. SAMUEL WILKS.
W. S. CHURCH. THOMAS WAKLEY.
THOMAS WAKLEY, JUN.

Owing to his absence in South Africa Sir WILLIAM MAC CORMAC was unable to sign the Report.

I find by the Bankers' Book that the actual balance on Jan. 1st, 1899, to the credit of the Fund was £318 5*s.* 8*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 2nd, 1899.

The balance at the Bank at the present date is the sum of £358 1*s.* 6*d.* I have also checked the receipts for disbursements and find the above account strictly accurate.

December 29th, 1899.

HENRY A. PITMAN, Hon. Auditor.

Obituary.

SIR JAMES PAGET, BART., F.R.C.S. ENG., F.R S., D.C.L. OXON., LL.D. CANTAB., &c.

IT is with deep regret that we announce the death of Sir James Paget, which took place at his residence, 5, Park-square West, Regent's-park, on Dec. 30th, 1899. He was in his eighty-fifth year and had been ailing for some two years past. On Christmas Day he went out for a drive, but since then had been confined to the house. All his family were in attendance, and at 10 o'clock on Saturday night he quietly passed away.

James Paget was the eighth child of Mr. Samuel Paget of Great Yarmouth and Sarah Elizabeth his wife, daughter of Mr. Thomas Tolver, of Chester, and was born in 1814. He was educated at a private school at Yarmouth. When quite young he was apprenticed to Mr. Costerton, a surgeon in practice in Great Yarmouth, and subsequently he entered as a student at St. Bartholomew's Hospital, where he studied under Stanley, Earle, Lawrence, and Vincent, who were full surgeons, while Wormald and Skey were assistant surgeons. Lawrence and Stanley both held him from the first in the highest esteem and assisted him in many ways. He became a Member of the Royal College of Surgeons of England in 1836, but it was as a first or second year's student that he discovered the trichina spiralis in the muscles of a subject in the dissecting room, his attention being attracted by finding small calcareous granules in the muscles. On pointing this out to Mr. Wormald, who was then demonstrator, the latter sent some specimens to Owen, professor of Comparative Anatomy at the hospital and assistant curator of the museum at the College, with the following note, dated Feb. 3rd, 1835:—

> DEAR OWEN,—I send you some sort of organised being, as I believe, which occupies the muscles of a subject under dissection at St. B. H., and as I know you are a keen hand for parasitical things, from "crabs" downwards, I send the enclosed for your inspection.
>
> Ever yours sincerely,
> THOS WORMALD.

On examining the cysts under a microscope Owen at once discovered the "worm," which he named trichina spiralis. But in the meantime Paget, who had no microscope of his own, at length managed to get the use of one from Mr. Robert Brown of the British Museum, and he confirmed a previous conclusion he had come to by means of using a pocket lens—namely, that the cysts did contain worms. On Feb. 6th, 1835, he read a paper on the subject before the Abernethian Society, Dr. Arthur Farre being in the chair. It was not until some days after this (Feb. 24th) that Owen, who had in the meantime accurately described and classified the worm, read his paper before the Zoological Society, and in this paper, with that transparent sense of honour and justice so characteristic of the man, he gave full credit to the then unknown and undistinguished student for priority of discovery. Paget's own description was, to use his own words in a letter to THE LANCET of March 10th, 1866, "not indeed complete—but I believe not inaccurate, except in a blundering endeavour to assign its zoological relations." So to Paget belongs the credit of having been the first to see the worm, though Hilton of Guy's Hospital had some time before this suggested that "the specks probably depended upon the formation of very small cysticerci." Owen's discovery was made quite independently.[1]

Sir James Paget's career as an active member of the staff of St. Bartholomew's Hospital lasted for twenty-eight years—namely, from May 30th, 1843, when he was appointed lecturer on general anatomy and physiology, to May 11th, 1871, when he resigned the office of surgeon and was appointed honorary consulting surgeon. On Oct. 2nd, 1843, he was appointed warden of the Hospital College, an important and, to one like Paget with a high ideal of duty, a most responsible post. In the following year he married Lydia, daughter of the Rev. Henry North, domestic chaplain to H R.H. the Duke of Kent, and he and his wife lived in the College rooms, which cannot be called palatial even now, and were most probably worse fifty years ago. In these early days he was very poor, and he eked out his scanty income by writing articles in the "Penny Cyclopædia." Following out his own maxim, "A man must work within an inch of his life," he had no real holiday for seventeen years, was rarely in bed before 2 A.M. and rose at 7.30 A.M. In 1846 he was asked to report upon the anatomical museum as curator, and the result of this report was the first volume of the catalogue. For this he was presented by the Governors with the sum of 150 guineas. On Feb. 11th in that year he was admitted as a candidate for the office of assistant-surgeon, and on Feb. 24th was elected to that office, not without strong opposition, for he had never been apprenticed to any one of the surgeons, neither had he been house-surgeon, and it was mainly owing to the help and support which he received from Sir William Lawrence that he succeeded. The figures were as follows: Mr. Paget, 142 votes; Mr. McWhinnie, 78; Mr. Pennington, 22. At about this date Mr. Stanley, who had seen and admired Paget's work as curator of the hospital museum, recommended him for a similar post at the Royal College of Surgeons of England in the department of pathology, and it was due to the experience gained at this post that Paget was able to write his unrivalled lectures on surgical pathology. He had been elected a Fellow of the College in 1843. From 1847 to 1852 he also held the post of Arris and Gale professor of human anatomy and surgery. To return to his hospital work: in 1851 he resigned the office of warden, and in 1859 the lectureship on general anatomy and physiology; in 1861 he was elected full surgeon, and in 1865 he was appointed lecturer on surgery, a post which he held until 1869. In 1865, too, he was elected as a member of the Council of the Royal College of Surgeons of England, a post which he continued to hold for ten years, until in 1875 he was elected to the office of President. In the following year he was chosen as a representative of the College upon the General Medical Council, an office which he continued to hold until 1881. On resigning the post of surgeon to St. Bartholomew's Hospital he was at once elected consulting surgeon, a copy of the resolution of the Court of Governors being presented to him by H.R H. the Prince of Wales, President of the hospital. In 1877 he delivered the Hunterian Oration, the Prince of Wales being among his auditors. The subject was, "The Life and Teachings of John Hunter." As year after year the time for the Hunterian Oration comes round it is increasingly difficult for the selected speakers to find anything new to say, but Paget always had the faculty of being able to throw fresh light upon a subject, and to make matter however well worn interesting by his charm of style and diction. The concluding sentence of the oration is worthy of Thackeray: "His true thoughts still live in us, and they will live beyond us, never ceasing to urge and help men onwards in the pursuit of truth, for in the world of mind he that is mortal may produce that which may have immortality." In 1882 he delivered the Bradshaw Lecture, taking as his subject "Rare Diseases"; in 1885 he was elected a trustee of the Hunterian collection; and in 1887 he was appointed Morton lecturer on Cancer and Cancerous Diseases. We have already traced his career as an active member of the staff of St. Bartholomew's Hospital, and have mentioned the paper read while he was still a student upon the trichina spiralis before the Abernethian Society; nearly sixty years later he delivered the address upon the occasion of the centenary of that society—namely, in 1894.

As the circumstances which led to Paget's resignation formed the subject of one of his most interesting lectures it will be well to recapitulate them. Early in the year 1871 he contracted blood-poisoning, to all appearance through the unbroken skin, during the performance of a post-mortem examination. The result of this was a diffuse cellulitis affecting the right hand, arm, shoulder, and back. For many weeks he lay between life and death, but finally, owing to a good constitution and the assiduous attention of nearly the whole staff of the hospital, he recovered, though the attack permanently weakened his powers of resistance. Feeling unable to continue to do justice to the work of surgeon he resigned—a resignation accepted with great regret by the committee, and on July 4th, 1871, H.R.H. the Prince of Wales, as President of the hospital, presented him with an illuminated address embodying a resolution of the Court of Governors expressive of their sincere regret at his resignation and their unanimous thanks for his long and valuable services. He received a baronetcy in the same year.

Of his writings it is necessary to do little more tha

---

[1] THE LANCET, Nov. 18th, 1882, p. 869, et seq.

Very truly yours

James Paget

mention their names for they are known throughout the scientific world as models of what scientific papers should be. Clear, accurate and sound in every respect, they are also written in a style which makes them most pleasurable reading and which at the same time impresses the subject firmly on the memory. His earliest work in this direction was the paper upon the trichina spiralis read before the Abernethian Society in 1835. In 1846 and 1851 appeared respectively the first and second volumes of the catalogue of the museum of St. Bartholomew's Hospital. In 1849 he published "Lectures on the Processes of Repair and Reproduction after Injuries"; in 1850 "Lectures on Inflammation"; in 1851 "Lectures on Tumours"; and in 1853 his great work "Lectures on Surgical Pathology," material for which he had gathered together during his tenure of the post of curator of the Museum of the Royal College of Surgeons of England and Arris and Gale lecturer. To the first edition of Holmes's "System of Surgery" Paget contributed articles on Sinus and Fistula, Ulcers, Tumours, Contusions and Wounds. In 1875 was issued a volume edited by Mr. Howard Marsh, entitled "Clinical Lectures and Essays," being for the most part reprints of papers contributed to THE LANCET or read before societies. Besides these there were numerous addresses delivered at the hospital and elsewhere.

It is no easy matter to attempt to appraise at its correct value the contribution which Sir James Paget has made to our knowledge of surgery and especially of surgical pathology, and this is so not because anyone who is conversant with the work he did can be in any doubt as to its great importance but because he is responsible for so much which has become part and parcel of our knowledge of surgical pathology. He was pre-eminently a clinical pathologist, for he united in himself the pathological knowledge derived from his work in the museums of St. Bartholomew's Hospital and the Royal College of Surgeons of England, with the experience of a practising surgeon, and at a time when the general introduction of the use of the microscope into the examination of morbid tissues and products was leading to an over-estimate of the value of structural details Paget saw clearly that the mode of life of a tissue was as essential a part of its being as was the arrangement of its constituent fibres and cells; so in his "Lectures on Surgical Pathology" he wrote: "The examination of any texture, morbid or healthy, cannot be regarded as complete if it is limited to a mere determination of its form, appearance and structure. Its growth, development, tendencies, influences upon the individual in whom it occurs, in short its life, must be attended to. Its teleological as well as its morphological aspects are to be considered." The same closeness of observation and scientific curiosity which prompted the young student of anatomy to investigate more closely the minute calcareous nodules which he saw in a muscle made the surgeon examine carefully all the cases which came to him for treatment. An excellent memory and assiduous note-taking enabled him to compare one case with another and to put like with like, and thus he recognised as definite diseases morbid conditions which had doubtlessly been seen many times and yet had been passed over unheeded by others. Paget it was who first described the fine soft appearance of the skin which is liable to follow an injury of a sensory nerve and the phrase "glossy skin" which he applied to it is now the most usual name for this fully recognised characteristic of a nerve lesion. He had a faculty of happily naming and the name "myeloid" which he applied to giant-celled new growths has completely displaced their former appellations though he was not the first to describe these tumours. There are several instances of the fruits of this happy combination of a skilful pathologist practising as a surgeon, but perhaps the most interesting is the account he gave of "recurrent fibroids"; those who are familiar—and what surgeon is not?—with the account he has given in his lectures on surgical pathology of the tumour to which he applied this name will acknowledge that no better description could be given of this important variety of tumour now classed among the sarcomata. There are, however, two morbid conditions with which Paget's name is most closely connected, and it is to his account of [illegible] that the future remembrance of his name will be most [illegible] due. The phrase "Paget's disease" is equally applicable to the disease of the nipple now often called [illegible] dermatitis and to that affection of the bones to which he applied the name of "osteitis deformans." The account of the disease of the nipple first appeared in 1874 and confirmatory evidence of the truth of the description and of the tendency to result in carcinoma was soon supplied by others. In 1877 he read a paper before the Royal Medical and Chirurgical Society on "Osteitis deformans," and although our knowledge of the disease has of course increased the accuracy of the account has not been surpassed. We cannot but think that a valuable lesson may be learned from Paget's professional life, the fuller the knowledge of pathology which a surgeon possesses the more fitted will he be for his work as a surgeon, and if this was true of the earlier part of this century it is even more true now.

The well-known Handbook of Physiology which was given to the world under Kirkes's name was mainly by Paget. It was the outcome of the course of lectures on physiology which he delivered in the medical school of St. Bartholomew's Hospital from 1844 to 1848. So far as is now known he handed over his "notes," which were in fact the whole section for the day's lecture carefully written out, to Kirkes, giving him the credit of editing and publishing the work. His name appears on the title page of the 1848 edition as "assisting" Kirkes and his notes are acknowledged in the preface. Kirkes, of course, made additions of his own and brought the work up to date. Sir James Paget's last publication was the "Echoes from Old Case Books," which, although published in 1891, dealt with his surgical experience only up to 1870, when from want of leisure his case books had in great part to be given up. He was more interested in pathology than he ever was in physiology and he used to collect specimens from the post-mortem room during the first five days of the week and give a most interesting lecture on the Saturday. The lecture room was always full, but on Saturday morning at 9 A.M. it was crowded and the interest taken in the "Pathology" lecture was very great.

Paget was for many years one of the best—if not the best—speaker in the profession and a friendly rivalry upon this matter was maintained between himself and his colleague, the late Sir William Savory. Both were admirable speakers, both took the greatest pride in their art and both took infinite pains with their speeches and addresses, even going so far in some instances as to learn them by heart. Both were able to speak for an hour or so without hesitating or ever using any but the word most fitting for its particular place. But despite the similarity in preparation the delivery of the two was markedly different. Savory gave the hearer the effect that he was listening, as he was, to a prodigious *tour de force* of memory—in other words, the listener felt that the speaker had learned his speech beforehand. With Paget, although the speech or address had most likely been written out two or three times and learned by heart, when he came to deliver it it appeared as though he were speaking just as the words came into his head—although he never showed any really rhetorical force, but the speech flowed on in an even stream of musical and well-balanced sentences. He could speak without preparation, however, and was most ready in either proposing or responding to a toast.

As a surgeon he was a very keen observer and one who took unbounded trouble, and his opinion was most valuable, especially in rare cases, for he saw a large number of them and never forgot what he had seen. As to personal characteristics he was strongly and deeply religious in the best sense of the word and would have been a great theologian if he had not taken up a different line of thought. In 1880, at the invitation of his son, the present Vicar of St. Pancras, but then Principal of the Clergy School at Leeds, he delivered an address at the Leeds Theological College to the candidates for ordination. Taking for his subject Theology and Science he laid down and supported the thesis that the more a man knew of science the more was it possible to reconcile its facts with religion. To a natural capacity for work he added habits of exactitude and punctuality in all that he did, thereby increasing his opportunities for doing work. He was careful and frugal, with absolutely no ostentation, and he never shirked [illegible] to save himself [illegible] when very busy with a large practice he was President of the Royal Medical and Chirurgical Society and of the Clinical Society of London as well as of the Royal College of Surgeons of England [illegible] Dublin. In this respect the late Sir A. Clark [illegible] Sir W. Jenner [illegible]

As a consultant Sir James [illegible] a great point of being punctual [illegible] more than two or three minutes late. [illegible] that he did [illegible] was largely owing to his [illegible] of duty [illegible] that would he do. at whatever cost. It was, however, due in part to his personal modesty. His view was that he had no right to keep either a patient or a practitioner waiting. But it was also partly due to the fact that he was well aware that punctuality was a great economy, not only of other people's time. but of his own as well. However pressed he might be he never evinced hurry, but seemed entirely at the disposal of his patient. Yet there was some art here. For by his earnestness and his power of leading he quickly made his way to a clear issue, and established the impression that all had been well considered and determined upon, and thus talk which was useless and a waste of time naturally died away. His charm of manner, all who knew him will agree, was as telling in the sick-room as elsewhere. His voice was clear and musical; he spoke distinctly, and in pure and strong English. and always with a frank and sympathetic kindness which inspired confidence and grateful recognition.

Towards the practitioner in the case he was always in the highest degree considerate and courteous, and though it was well known to everyone that he was the first surgeon of his time and a man of European reputation he seemed himself entirely unconscious of the fact. In the early days of his practice his opinion was anything but a strong one. He had never been house surgeon and had been occupied chiefly with physiology and pathology. Yet he rapidly advanced, for he was aware of defects which were unknown to others and he was intently observant. Thus he never repeated a mistake and always appropriated any information that came within his reach and kept it fresh and ready for the next occasion. Later he stood by common consent without a rival, for he was himself the fountain of knowledge in many fields of pathology. Such subjects as inflammation, diseases of bones, and malignant growths he had made peculiarly his own, and he had made his mark by original observations in the field of surgery as a pioneer in the study of injuries of nerves, chronic pyæmia, senile scrofula, osteitis deformans, &c., and he possessed in a very rare degree the faculty of estimating the relative value of the facts which presented themselves and of arranging and balancing evidence so as to arrive at a sound conclusion. He was often right when others were wrong, either because his knowledge was altogether superior or because he saw what others had overlooked. At the present day the tendency often is to study merely the processes of disease and to ignore the characteristics of the patient in whom the disease is at work. In this connexion a useful lesson might be learnt from Sir James Paget, who, while he carefully noted every feature in the malady, regarded the patient himself as an important factor from the point of view alike of diagnosis and treatment.

His honours and appointments were many and varied and though we have mentioned most of them we may fitly recapitulate them here. Besides the posts held at St. Bartholomew's Hospital, which we have already mentioned, he was consulting surgeon to Christ's Hospital. At the Royal College of Surgeons of England he was elected a Fellow in 1843, a member of the Council in 1865, and President in 1875. He was never an examiner for the College although he filled that office for some time on the Army Medical Board. He was Serjeant-Surgeon to the Queen from 1877, surgeon to the Prince of Wales from 1863, and a Corresponding Member of the Institute of France. In 1871 he was created a baronet, and was Vice-Chancellor of the University of London from 1884 to 1895

Possibly the greatest honour in a scientific sense which fell to Paget's lot during his long and noble term of life was his being chosen as President of the International Medical Congress which met in London in August, 1881. His presidential address will never be forgotten by those who heard it, and it stands out pre-eminently even in the company of the magnificent addresses of such speakers as Virchow and Huxley, Michael Foster and Gull. Can there be a more eloquent call to arms for us who are left than these words of him so lately passed away? "And then let us always remind ourselves of the nobility of our calling. . . . . We had better not compete when wealth is the highest evidence of success: we can compete with the world in the nobler ambition of being counted among the learned and the good who strive to make the future better and happier than the past. And to this we shall attain if we remind ourselves that, as in every pursuit of knowledge there is the charm of novelty and in every attainment of truth utility, so in every use of it there may be cha[illegible] I do not mean only the charity which is in hospitals or in the service of the poor, great as is the privilege of our calling in that we may be its chief ministers, but that wider charity which is practised in a constant sympathy and gentleness, in patience and self-devotion. And it is surely fair to hold that, as in every search for knowledge we may strengthen our intellectual power, so in every practical employment of it we may, if we will, improve our moral nature; we may obey the whole law of Christian love, we may illustrate the highest induction of scientific philanthropy."

These words are eminently characteristic of him who uttered them—nobleness and gentleness were part of his being. In no way narrow or bigoted, he was great-souled, honest, and upright, with a reverence for truth and a hatred for shams or deceit of any kind. Yet he was never wanting in tact and had a wonderful faculty for telling the truth without hurting people's feelings. In the guest room of an ancient Spanish monastery hangs a notice to the effect that the Abbot trusts that anyone who shall come there will behave himself as a gentleman and a Christian. Paget was a shining example of both, this world is the poorer by his passing, but his memory will ever remain to inspire us who are left with courage in our daily work and with sympathy for those who fall by the way.

The first part of the burial service for the late Sir James Paget took place on Thursday, Jan. 4th, in Westminster Abbey, at 2 P.M. The body was afterwards conveyed to Finchley Cemetery for interment. Dr. W. S. Church, President of the Royal College of Physicians of London, was unavoidably absent through illness, and the College was represented by Dr. Pye-Smith, Senior Censor.

HENRY THOMPSON, M.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON TO THE HULL ROYAL INFIRMARY.

MUCH regret has been occasioned among the many friends of Mr. Henry Thompson by the announcement of his death after a short illness, at the age of 49 years. Mr. Thompson, who began his professional life as a pupil of Sir Robert Craven, was afterwards a student at St. Bartholomew's Hospital, where he held the office of house physician and took several prizes. Becoming M.R.C.S. Eng. in 1871 and L.R.C.P. Lond. in 1874, he was shortly afterwards elected house surgeon to the Hull Royal Infirmary, and assisted the late Dr. Kelburne King in carrying out the antiseptic method of Professor Lister just then introduced. In 1878 he was appointed honorary assistant surgeon, and in 1886 honorary surgeon to the infirmary, continuing in office to the time of his death. He was also surgeon to the 1st Volunteer Battalion East Yorks Regiment for 20 years, receiving on his retirement promotion to the rank of Surgeon Lieutenant-Colonel, and had been President of the East York and North Lincoln Branch of the British Medical Association. Through his whole career Mr. Thompson was noted for conscientious and strict devotion to his profession, of which he was an exceedingly able and successful practitioner. His ability and uprightness also won for him the respect and esteem of his professional brethren, by whom, as well as by his patients, the loss is much felt. He leaves a widow and large family, the eldest son having only just entered as a student at the Middlesex Hospital.

THE WAR IN SOUTH AFRICA.

SINCE we last wrote on this subject there have been some successes on the British side, but not of such a decisive or important kind as materially to affect the result. At present there is a war lull. The campaign in South Africa, besides causing us to raise the eyebrows of astonishment, as the Germans say, at the resources and preparedness of the Boers, has taught us and the world at large some useful and important lessons. It shows, to begin with, the enormous strength of even a small, but determined, nation or race in defensive warfare when armed with the most modern weapons and fighting on its own particular methods. Our checks and reverses in South Africa are a valuable object-lesson. The thought will at once occur how extremely difficult, even assuming our fleet to be disabled, would be an invasion of this country and how difficult, too, would it be for an invading army, after succeeding in effecting a landing, to get away again, if our adult population were only properly armed and organised and our land defences in an effective condition. The salient features of the present war in South Africa are noteworthy. The Boers knew their own mind, they had long foreseen what would happen, and they were prepared for it; they armed themselves with all the latest and most destructive engines of war and they adopted a new system of tactics singularly well adapted to their purposes, the country, and the nature and circumstances of the campaign; whereas our undecided and vacillating policy and our ignorance of their carefully planned designs and preparations greatly tended to aid and facilitate the Boers in carrying them out. Moreover, the huge area of the theatre of war, in a disaffected if not hostile country, thousands of miles distant from us, the extreme weakness of the British garrison in South Africa at the time of the ultimatum, and the comparative absence of any adequate land transport when the reinforcements arrived there, compelling us to hug the railways—these were all strong points which were eminently favourable to the initial success of the Boer rebellion. No doubt political and military blunders may have been committed, and the difficulties and formidable nature of our undertaking in South Africa have evidently been underestimated, but we very much question whether the army of any other nation would not have passed through a very similar experience under the same circumstances or would have fared much better than we have done. It is certain that no other Power in the world could have successfully transported in a similar space of time and under similar conditions so well found and equipped a force as that which has been, and is still being, landed in South Africa. And after all, while giving every credit to the enterprise, tactical skill, and defensive ability displayed by the Boers, what have been the advantages that they have hitherto gained which are likely to affect the ultimate result? They have "hung up" and rendered ineffective for a time a large number of British troops and besieged, but not yet captured, certain garrisons with a result which is certainly anything but flattering to our arms in the meantime. The Boers have, nevertheless, failed in the great strategical object open to them—namely, to interpose a big force to the southward and take or threaten the port of Durban.

It is indubitably a very serious and formidable war. But the lesson to be read from the present situation has not been lost upon this nation. It has had the effect of welding together the separate units of the empire and all classes of society in a way that nothing else could have brought about. Henceforth the Boer entrenchments will no doubt be shelled by British artillery after a fashion to which they have not yet been subjected, while a large column of our army will in all probability soon be concentrated and organised for the invasion of the Free State and a march upon Bloemfontein or through the Transvaal to its capital—to say nothing of the constant harassing of the enemy's troops and lines of communication by the bodies of cavalry, mounted infantry, and field artillery which will soon be put into the field. Things will assume a very different aspect when we follow the same kind of tactics and fight with the same weapons as our foes. For this the so-called irregular forces are admirably adapted, and for fights in the open and on the plain there are no better troops in the world than our British infantry and field artillery. The fact is, that the judgment of the British public has been unduly influenced by the more speedy and decisive results of our campaigns elsewhere under altogether different conditions and where there had been time to make all our plans and perfect our arrangements beforehand. The Lord Mayor struck a happy and right note in his speech to the Volunteers at the Guildhall when he said: "It is a vexed question whether the first day of this January ushers in the new century, but it is beyond doubt that you to-day have inaugurated a new era in our national history;" and, again, when he added that we have been forced to the arbitrament of war and that we shall not sheath the sword until our supremacy in South Africa is established—a supremacy which will be universally welcomed as securing in that country the equality before the law of all nationalities, and in consequence real freedom in its fullest and only true sense. Despite the utterances of the foreign press we may be sure that the Continental governments take a more sober and correct view of the situation and are duly impressed with the attitude and the actual and potential capabilities of this country. We must apologise to our readers for having been led into saying so much, but we think that people in this country are not in a position to form anything like a fair or proper estimate of the reasons which have influenced the generals in the field, or as to what the present or future situation will be, although the nation may still have to exhibit some fortitude and "staying power" until it is reached.

The Government has made an addition to the civil staff of consulting surgeons for the field. As we announced last week the following surgeons have been appointed to proceed to South Africa:—Sir William Stokes, surgeon-in-ordinary to the Queen in Ireland, and surgeon to the Meath Hospital, Dublin; Mr. Watson Cheyne, surgeon to King's College Hospital, and professor of surgery in King's College, London; Mr. G. L. Cheatle, assistant surgeon to King's College Hospital, and teacher of practical surgery in King's College; and Mr. Kendal Franks, late senior surgeon to the Adelaide Hospital, Dublin, and surgeon-in-ordinary to the Lord Lieutenant of Ireland. Sir William Thomson, ex-President of the College of Surgeons in Ireland, is also proceeding to South Africa as the principal surgeon of a special hospital there; and Sir John Furley is likewise embarking for the theatre of war where his services and experience in connexion with ambulance work will be of much value.

We regret to notice that the deaths from enteric fever in Ladysmith are mounting up and that the outbreak of this fever in that garrison is apparently a somewhat severe one. Dysentery is likewise prevalent among the troops to some extent. We are extremely glad to learn on all sides that the wounded in South Africa generally are doing well; indeed, their progress is highly satisfactory. Many of the more slightly wounded will soon be fit to return to field duty. The climate is described as very favourable for their treatment, and it is needless to add that antiseptic surgery is universally adopted in the field and at the various war hospitals. Our casualties, as we have already said, have not so far been heavy when calculated on the whole force. We hear very little indeed, as might be expected, as to the number of sick and wounded among the Boers, and we understand that the Transvaal Government has only recently begun to publish any statistical and nominal returns of those who have died. What with the exposure in the field, the difficulties of food-supply, the prevalence of dysentery, and the amount of fighting which has taken place there must inevitably have been a large amount of inefficiency among them from various causes.

The number of sick and wounded in the various British hospitals will have severely taxed the organising and administrative capacities of the medical staff in South Africa, and when all the troops, transports, and supplies of all kinds arriving at the Cape are taken into account it may be readily imagined that the strain and labour entailed upon all are enormous. We notice that in speaking of the hospital accommodation at the Cape, the special correspondent of the *Times* recently alluded to the existence of complaints about the military hospital accommodation at Cape Town. While acknowledging the admirable skill and care of the medical officers, the correspondent considered that the hospital establishments had been calculated on too small a scale and that improvement in the organisation of the arrangements was required. This is not, we think, surprising under the circumstances. No one at the beginning of the war formed a correct, or even approximately correct, calculation of all that has since taken place. The existing buildings and hospital accommodation had to be made available, and it necessarily takes time under such conditions as prevailed at Cape Town to adjust matters to them and to the requirements of the occasion. British officers and soldiers generally have, as we know, very vigorous appetites when they are not really sick or when their wounds are relatively slight, and it is, per- haps, the simplest and most economical plan in the end to follow the practice adopted by the Americans in their war hospitals at the time of the rebellion and pro- vide the amplest food supplies for all suitable cases. The head of a big military hospital requires all the organis- ing and business qualifications which would fit him to undertake the management of a large hotel under the most trying circumstances. The wounded and sick from the Cape are arriving in this country and the preparations for sending out new divisions to the seat of war are proceeding apace. We publish this week some more [illegible] from Sir William MacCormac as well as contributions from our Special Correspondents.

(NOTES FROM SIR WILLIAM MACCORMAC.)

Sir William MacCormac has very kindly sent us the following additional notes, which, written as they were under circumstances of great difficulty, we are certain our readers will appreciate.

After seeing all that there was to be seen of medical interest at Cape Town and hearing that it was uncertain when active operations might take place in the Kimberley direction it appeared to me that I might usefully employ my time by going to Durban and inspecting the hospital arrangements on the line towards Ladysmith, and perhaps accompanying the force marching to its relief. In this proposal the principal medical officer cordially concurred, so I left Cape Town in the *Briton* and arrived in Durban, a distance of 1000 miles, on Tuesday afternoon, Nov. 28th. On disembarking I found that the base was established at Pietermaritzburg, some 70 miles in the interior, and there I decided to go on by the night train, arriving in Pietermaritzburg about 8 A.M.

The country, when it became light enough to see it, looked very fertile, beautiful, and very green. Pietermaritzburg, the seat of the Natal Government, is a very clean, wide-streeted, pretty town. The houses have for the most part gardens around them filled with ixias, lilies, roses, and many flowering shrubs, amongst them the beautiful hibiscus. Everything seems to flourish in luxuriance.

General Buller is staying with Sir Walter Hely-Hutchinson at Government House, where I had the pleasure of again meeting him. His preparations are being completed and he will probably advance early in the coming week on the road to Ladysmith. If the Boers dispute his passage, as they doubtless will, there must be heavy fighting and serious loss in crossing the Tugela river.

Dr. P. C. Sutherland, an old practitioner, now of some 30 to 40 years' residence in the colony, told me that soon after his arrival he was directed by the Government to make an inquiry into the diseases of the natives, who are chiefly Zulus, and that he found an entire absence of phthisis or any form of tuberculous disease, but that now these are very prevalent amongst them, which he attributes to inoculation by phthisical Europeans. The manner of getting about here is by ricksha, as in Japan and other places. The Zulus who draw these rickshas are men of splendid physique, and many are quite handsome. Yet they die young, many from pneumonia, others from heart disease. It is not a use to put a man to.

I send you a further brief account of some interesting and some remarkable cases in the hospitals here. On Dec. 3rd the thermometer stood at 98° F in a verandah in the shade, a very oppressive heat. I am almost immediately going on to Estcourt and Colenso, where fighting must shortly take place.

On the way from Cape Town to Durban the ship called for a few hours at Port Elizabeth and at East London, whence railways reach the border between Cape Colony and the Free State.

Port Elizabeth, Nov. [illegible].—I went ashore and visited the Drill Hall, which is equipped for a small base hospital. It is a lofty hall, 112 feet by 81 feet, and contains 50 beds, which might be increased to 70. There are three small isolation wards in the hospital which is in charge of two civilian surgeons. There are a few sick from the 1st Welsh Fusiliers who arrived by the *Kildonan Castle* the day before.

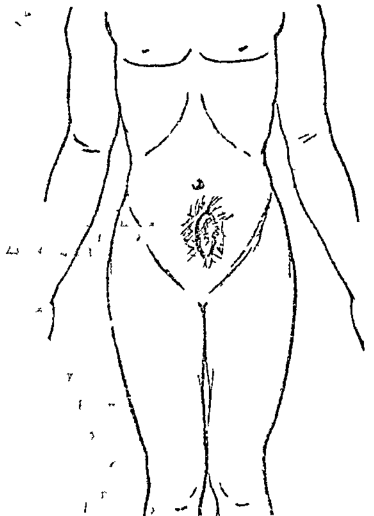
East London, Nov. [illegible].—I went ashore, being lowered into the tender in a basket, and returned the same day—a novel and rather disagreeable experience—and I inspected the hospital ship *Trojan* lying in the Buffalo River here. It contains 72 beds for serious cases besides accommodation for 70 convalescents and accommodation for 18 officers—one beautifully fitted ward with five cots, the rest being placed in state rooms, some with only one cot, but mostly with two. There is a general ward aft with 37 cots, hung fore and aft to swing. The majority of patients, however, prefer fixtures. There is ample lavatory and bath accommodation. There is a lift to convey the patients on their stretchers from the upper to the main deck and a very easy inclined plane with steps for invalids going up or down or for carrying stretchers easily. There is room for 50 convalescents on the troop deck and accommodation there also for the Royal Army Medical Corps men. The operating theatre is very conveniently arranged and is amply supplied with sterilising apparatus, instruments, and antiseptic material. A small ward adjacent serves for special operation cases. The smoking-room of the ship is converted into a day-room. There is a steam laundry, pharmacy, electric light throughout, and electric fans which have the effect of cooling the air—or, rather, of making it feel cooler. The ship is lighted throughout by electricity.

There are three surgeons—Major Hart in command, and two civilians—and there are three nursing sisters, who have excellent quarters reserved for their exclusive use, and 21 orderlies of the Royal Army Medical Corps. The "Hopper," with Jay's disinfectant, carries off all excreta. The whole ship is admirably fitted and arranged and its present purpose is to serve as a base hospital for General Gatacre's division. It looks most comfortable and even luxurious. A non-dieted hospital is being equipped ashore in the Drill Hall and as soon as it is ready Major Hart will send the present cases ashore. They number about 14, chiefly venereal and quite unsuitable for a hospital ship.

Durban, Nov. 28th.—Just as we arrived at 2 P.M. the *Spartan* hospital ship was moving out for Cape Town. I landed about 6 P.M., and finding that the base was at Pietermaritzburg I decided to go on by night train. Major McCormack made everything very easy for me, and I reached that place about 8 A.M. to-day. I found Colonel T. J. Gallwey, P.M.O., waiting for me at the station; he is brother of Colonel Gallwey of the Somersets. I visited with him in the afternoon the hospital in the Legislative Assembly building, fitted with 50 beds as a temporary hospital. The large meeting hall contains wounded and sick—both from dysentery and fever. In one case of gunshot the bullet entered on a level with the tubercle of the tibia, about an inch to the fibular side, and emerged through the middle of the fold of the corresponding buttock. The man was running at the time in a charge. In another case a bullet entered just above the left clavicle and passed out behind, about two and a half inches below the angle of the scapula or about the ninth rib, causing a furrowing wound in the soft parts. Empyema followed, and the man had rigors, but effective drainage was possible through the posterior wound, which was large, and the patient is now doing well. In a third case a curious flesh wound was caused by a bullet which passed transversely across, entered the anterior surface of the left shoulder, emerged below the centre of the clavicle, entered again beneath the right clavicle, and crossed the anterior portion of the right deltoid, to emerge in a position exactly similar to where it entered, causing four quite symmetrical wounds. There were no symptoms. The patient made a rapid convalescence. There were several wounded from the armoured train, chiefly by splinters of shell. One had received six such wounds in the lower extremities. There were also two severe scalp wounds. There are in all three wards: the large one already mentioned in the large meeting room of the Assembly and two smaller ones for officers. In these were four convalescent officers suffering from sickness. The staff consists of Major Browning, R.A.M.C., two civilian surgeons, and five nursing sisters from Johannesburg. At the present time there are 38 cases in this hospital.

I then went to visit the College Hospital in a large new school building. This contains four wards and supplementary stationary hospital in tents—marquees for eight beds and bell tents for three stretchers. This is an addition to the hospital proper, which has 70 beds. There are three surgeons—one of the Royal Army Medical Corps and two civilians, one being an old student of mine in Belfast from Johannesburg. There are also four nurses not belonging to the Army Reserve. The sick and wounded were chiefly from the Imperial Volunteer forces. One young fellow about 20, admitted on Nov. 24th, was shot in the thigh at Mooi River on Nov. 21st. The bullet entered near the middle of the fold of the buttock and emerged, after fracturing the femur, at a little below the centre of the inner aspect of the thigh over the course of the femoral artery. He was dragged along, he says, by two comrades for two miles before aid was reached. The foot is stated to have been very cold on arrival here, and it was more than doubtful if any pulse could be felt in the posterior tibial artery. When I saw it the foot was cold and discoloured—reddish brown; evidently gangrene had set in. The question was should amputation be performed, and where? On the 30th the discolouration was more pronounced. The temperature on the previous night was 102° F., on the morning of the 30th it was 99·6°. I advised amputation.

On the 30th I visited Grey's Civil Hospital. Dr J F. Allen, a practitioner of 30 years' standing at Pietermaritzburg, is in charge. There are 80 beds in two large wards and a dozen smaller wards containing two, four, and six patients each 100 patients were treated there after the fights at Dundee and Elandslaagte There are now many enteric cases Zulu natives and East Indians, who mutually despise each other and quarrel. There is a very good operating room. One very interesting case is that of a man of 24 years of age, wounded accidentally at the firing butts at 400 yards range with a Lee Metford bullet on Nov 1st The bullet entered behind passed through the right sacro iliac synchrondrosis, and emerged half way between the anterior superior spine and the ninth costal cartilage after traversing the cæcum The man was wounded at 11 A M and had to be carried back a distance of nine miles in an ambulance waggon At 7 P M Dr Allen made a vertical incision five inches long, the bullet aperture being in the centre, and traced its track until he came down upon the cæcum, in which he found two apertures OO close together, as if the ball had passed through a fold of bowel Some fæcal extravasation had taken place The wounds were invaginated and the bowel was closed over them with Lembert's suture and the posterior entering wound of the bowel was *similarly dealt with The abdomen* was flushed with boiled water, the wound closed, and drainage used All went well without any symptoms and the patient is up and convalescent Another case was that of a man wounded at Elandslaagte, presumably by a shell He has made a good recovery but there is now an opening communicating with the bladder about one and a half inches long and one inch wide (see illustration) All the urine escapes through this wound, which is surrounded with a cicatricial surface, and the floor is seen lined with the



red mucous membrane of the bladder The remarkable point is that the lower border of the present opening is one and a quarter inches above the symphysis pubis and it is difficult to see how the peritoneal cavity could have escaped. He has had however, no symptoms of any kind indicating that it was wounded The man could not remember whether his bladder was full or not at the time of the injury, which took place at Elandslaagte at the end of the fighting, by a bullet, as he believes, but this is not possible He lay on the field all the following night, but has made a good recovery and is now convalescent I should think that by freshening a wide surface all round the opening can be closed

I visited the Fort Hospital with the Principal Medical Officer (Colonel Gallwey, R A M C) in the afternoon

Dr. Maunsell of the School Hospital visited me this morning to consult about the poor fellow whom I have mentioned above The foot was already drying up and a line of demarcation was plainly marked Amputation was performed by *Dr Maunsell below the knee. It was the best and only chance* for him The patient was removed to this hospital as there were no operating conveniences at the College Hospital

Pietermaritzburg Nov 29th.

(FROM OUR WAR CORRESPONDENT)

I have just been over No 2 General Hospital at Wynberg It is composed of some 48 marquees besides officers' tents and other necessary erections Each of the afore named marquees accommodates six men—288 patients in all The site chosen for its location is just below and to the right of No 1 (*vide* large squares on the left hand of the plan in THE LANCET, Dec 16th, 1899 p 1690) Its water supply is simply a continuation of what I have previously drawn your readers' attention to and the arrangement for its drainage practically the same as adopted by its sister camp higher up the hill Colonel Duke is in chief command and to his zeal and activity the present perfect state of the camp owes its origin, Major Addison *being the secretary and registrar Major Lougheed has* charge of the Surgical and Major MacDonald of the Medical Division, assisted by Lieutenant Goldsmith and Lieutenant Newman—all officers of the Royal Army Medical Corps Besides these there are 12 civilian doctors with a nursing staff of eight sisters under the control of Miss Hardman The nursing staff appears somewhat inadequate to cope with the requirements of nursing so many wounded men who are there already—with many more to follow, but the difficulty will probably soon be bridged over by the arrival of nine more sisters who are coming out, and will reach the hospital in a day or so Colonel Duke, R A M C, having called my attention to the want of a large recreation marquee for the use of convalescents as well as to the desirability of having several verandah chairs some tobacco, cigarettes, matches books, fruit, eggs, and flowers for the use of patients I called on my return to Cape Town upon the editors of the leading local papers and by their generous assistance brought these wants prominently before the public, with the result that in a few days' time all these necessaries were forthcoming in profusion to brighten up the countenance of many a wounded soldier The latrines, two in number are placed one on each side of the camp They are elongated wooden walled metal roofed structures supplied with several galvanised receptacles on the dry earth system These buckets are emptied daily, all excreta being deodorised and disinfected A partition (wooden) divides these latrines longitudinally into two compartments One of these is used as a lavatory Down the centre of it runs a long narrow wash board covered with zinc, and just above this there are two rows of iron piping filled with several brass taps through which water is conveyed for washing purposes

The cook house deserves special notice It is a long roomy wooden and brick structure with a galvanised roof, conveniently located near to the men s sick wards In it there are two large cooking ranges and four independent boilers capable of turning out exceedingly well cooked food for about 400 persons Under a span roof at the back part of it there is a similar arrangement as before described in the latrines—with this exception, that in this well arranged scullery an ample and constant supply of hot and cold water being maintained by the double piping and taps enables the cleansing of plates and dishes to be carried out with scrupulous care and cleanliness

All dirty and used water, falling by natural gravity, is conducted by drains to soil pits some distance from the camp

At times the wind especially when its direction is S E, is both gusty and strong and the ordinary wooden tent peg proves unequal to the task of holding the marquee in position therefore long iron stays with square flat metal bottoms have to be requisitioned. These are to be cemented in brick work and will probably save the tents in the future

Each hospital marquee measures 14 feet by 20 feet inside and with its stays covers a space of from 30 to 50 feet, a clear approach of from 15 to 20 feet being preserved between each of them Standing regularly as they do in eight rows of six with their well defined approaches they present a very neat and most imposing appearance

As some operations had to be performed this afternoon I proceeded with Colonel Duke to the tent used for operating, a small marquee located just outside the wards. It is somewhat small for the requirements; but it is only a makeshift until a larger and more substantially built one can be erected. One must remember that under existing circumstances a great deal has had to be organised and carried out at short notice. The work that has already been got through and the state of preparedness shown so as to cope with any emergency reflects the very highest credit on all the officials concerned. There is no chaos here at any rate. In the centre of the tent is the operating couch, and on a side table placed in the corner all necessary sterilising, antiseptic, and other requisites are fully in evidence. Chloroform seems to be preferred to any other anæsthetic, but I noticed that ether was there should it be required.

By the kind permission of the chief and operating staff I was afforded the opportunity of seeing several operations performed during my stay, and the able and dexterous manner in which the various cases were operated upon, as well as the success which has followed the operations, speaks volumes—more than any words I could use—for the skill displayed by our military surgeons at the front.

The first case I saw brought to the operating table was that of a private soldier with a gunshot wound of the hand. The bullet, a Martini-Henry, had crushed the second finger of his right hand, the first phalanx being smashed to pieces. There was also so much destruction and sloughing of the soft parts that amputation at the metacarpal joint was performed. Chloroform was administered, the finger was neatly removed, the hand bandaged, and the patient put to bed in a few minutes.

The next case was also that of a gunshot wound. A soldier had been wounded by a Martini-Henry bullet in the leg. The bullet had entered about the centre, but rather to the right, of the tibia, and, taking a somewhat oblique course across its anterior part, bored through the muscles and made its exit at the back of the leg. A large abscess had formed along the track of it and was burrowing into the thick part of the calf. It was deemed advisable to thoroughly explore the condition of the parts and to let out pus if any should be found. The patient was soon under the influence of a moderate application of chloroform, and both the entrance and exit apertures being carefully enlarged a finger was passed down the abnormal canal at the point of entrance to feel a quantity of loose bone fragments lying some two inches from the surface. On the introduction of a pair of long-nosed forceps a piece of bone was easily extracted, smooth and quite denuded of periosteum. A reintroduction of the forceps brought away several more pieces of a lesser size with some blood-clots and pus. A long slender probe was then passed through the leg, followed by the insertion of a No. 1 drainage-tube. The track was syringed out with an antiseptic solution, bringing through the posterior opening a quantity of bone fragments and purulent matter. The drainage-tube was then securely fixed *in situ* with pins, the usual dressings and bandage applied, and the patient taken back to bed.

A third and very bad case was that of a compound comminuted fracture of a patient's left thigh-bone caused by an exploded shell, complicated by an attack of tetanus—happily the first that has so far occurred. A private was wounded some nine or 10 days since. On arrival at Wynberg No. 2 Hospital he was found to be in a most dangerous condition. An examination revealed the presence of a large, irregularly shaped wound on the upper and fore part of his left thigh; another similar wound could be seen on the upper and posterior part of the limb at the base of the buttock. From these wounds several large pieces of shell were extracted; but the state of the poor fellow's pulse and temperature did not warrant any more active measures being taken beyond giving him ease from pain and the application of antiseptic lotions and dressings. Yesterday, however, tetanic symptoms supervened and to-day (the 7th), in spite of the use of large and oft-repeated doses of chloral and anti-tetanic serum injections, the convulsive symptoms have not lessened, but are, if anything, increasing in frequency and force.

The patient was brought to the operating tent, chloroform was given, and he was soon under its influence, but the tetanic spasms, although lessened, were never brought completely under control. A careful examination of the parts was made to see if there was any chance of removing the limb at the hip-joint; only to discover the terrible nature of the wounds which he had received, and to prove conclusively that there was no chance of obtaining sufficient quantity of flesh in any direction to form a flap to cover the stump intended to be made. A long probe detected a large cavity running nearly back to the anus. It was wisely decided not to operate, but to return the sufferer back to his bed. His temperature stood at 99·5° F., whilst his pulse was 79. I can only say as far as my observation went, that the patient received every possible care from Civil Surgeon Suffield who has ward charge of the patient and every attention from the senior officers who have consulted on the case. It was found desirable to isolate him from any other surgical cases in order to avoid risk of infection.

A most remarkable case is that of a private of the Northumberland Fusiliers. He also was wounded about 10 or 11 days ago. The Mauser bullet entered his left temporal region, must have gone close to, or even through, a portion of his brain, and coursing diagonally across the back of the orbit made its exit in the centre of the right malar bone of that cheek. With the exception of some sanguineous effusion into the corner of his left eye there is nothing to indicate that the patient has received an injury of any kind whatever. He eats, drinks, sleeps, and sees well. He is a fine specimen of the genus "Tommy" and was quite humorous in describing the manner in which he received his injury.

Another case was pointed out to me by Colonel Duke in which a Mauser bullet had struck the man in the centre of his throat (pomum Adami), evidently coursed round the patient's neck (the discoloration of the integuments confirming this) on the right side, and passed out just at the centre of the back of his neck.

There have been already 185 cases admitted into this newly formed hospital. One patient died on Dec. 3rd just as he arrived from fractured skull. Another patient succumbed on the 6th from a gunshot-wound, the bullet perforating the colon. Six are suffering from dysentery, six from debility, and two have rheumatism. I am informed upon very good authority that our red Marine force fared rather badly in the last fight. No less than 50 per cent. of the force employed have been killed or wounded. The wounded are being treated at Simon's Bay Hospital.

News has just arrived of the unfortunate affair at Molteno, on the southern borders of the Free State, and that General Gatacre has been forced to perform a retrograde movement. That a considerable addition to our wounded may be expected is proved by the hurrying up of our hospital trains to the north, and as I am going up to the front in the first one starting I must ask you not to be disappointed if you do not receive a letter from me by next week's mail.

Wynberg, Dec. 7th.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

I have absolutely nothing to tell you this week; there have been no fresh engagements this side, and all our patients are doing well. We are clearing the hospitals as fast as we can in order to be ready for the wounded coming down from the engagements that may take place at any time before Kimberley. It has been raining here for the last 24 hours, and of course this has not added to the comfort of patients in tents. No. 3 General Hospital is open at Rondebosch and will take its share of work. A portion of No. 4 arrived yesterday but we do not know where it is going. Our anxiety is to know where the medical officers for the Fifth and Sixth Divisions are coming from, as at present there are 240 odd men of the Royal Army Medical Corps out here and there cannot be many more available. The bearer company in the transport *Ismore* lost all their gear and equipment and had a very bad time, but luckily no loss of life took place. Mr. Treves is up at East London, and Sir W. MacCormac is still at Durban, but is expected back. Mr. Makins is at Modder River.

Since writing the above the disastrous engagement at Stormberg and the big fight at Spytfontein have taken place and we are expecting a very heavy contingent of wounded in a few days from both sides of the colony, but with three general hospitals available there will be ample accommodation.

Dec. 15th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6784 births and 6016 deaths were registered during the week ending Dec. 23rd. The annual rate of mortality in these towns, which had increased from 18 9 to 22 0 per 1000 in the three preceding weeks, further rose to 27 5 during the week under notice. In London the rate was 29 9 per 1000, while it averaged 25 9 in the 32 provincial towns. The lowest death-rates in these towns were 17 6 in Huddersfield, 18 9 in Leeds, 19 4 in Burnley and 19 7 in Blackburn; the highest rates were 36 4 in Preston, 36 7 in Swansea, 38 9 in Plymouth, and 42 4 in Portsmouth. The 6016 deaths in these towns included 578 which were referred to the principal zymotic diseases, against numbers increasing from 422 to 501 in the five preceding weeks; of these 168 resulted from measles, 122 from diphtheria, 111 from whooping-cough, 80 from "fever" (principally enteric), 45 from diarrhœa, 44 from scarlet fever, and eight from small-pox. The lowest death-rates from these diseases were recorded in Croydon, Plymouth, Wolverhampton, Derby, and Huddersfield; and the highest rates in Salford, Blackburn, Sheffield, and Hull. The greatest mortality from measles occurred in Birkenhead, Salford, Preston, Sheffield, and Hull; from whooping-cough in Leicester, Liverpool, Bolton, and Salford; from "fever" in Portsmouth, Nottingham, and Preston; and from diarrhœa in Burnley. The mortality from scarlet fever showed no marked excess in any of the large towns. The 122 deaths from diphtheria included 54 in London, 15 in Sheffield, eight in Leeds, five in West Ham, and five in Portsmouth Eight fatal cases of small-pox were registered in the week ending Dec. 23rd in Hull, but not one in any other of the 33 large towns; five small-pox patients were under treatment in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, Dec. 23rd, was 2916 against numbers decreasing from 3578 to 3084 at the end of the five preceding weeks; 209 new cases were admitted during the week, against 294, 277, and 180 in the three preceding weeks. Influenza was certified as the primary cause of 69 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 646 in the five preceding weeks, further rose to 968 during the week under notice, and were 506 above the corrected average. The causes of 93, or 1·5 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20 0 and 21·5 per 1000 in the two preceding weeks, further rose to 22 6 during the week ending Dec. 23rd, but was 4 9 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17 9 in Aberdeen and 19·5 in Edinburgh and in Leith, to 24 8 in Greenock and 33 8 in Perth. The 690 deaths in these towns included 37 which were referred to measles, 14 to diarrhœa, 12 to whooping-cough, 10 to "fever," eight to scarlet fever, and three to diphtheria. In all 84 deaths resulted from these principal zymotic diseases, against 69 and 81 in the two preceding weeks. These 84 deaths were equal to an annual rate of 2 8 per 1000, which was 0 2 above the mean rate in the previous week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 28 and 31 in the two preceding weeks, further rose to 37 during the week under notice, and included 20 in Glasgow, eight in Greenock, and five in Dundee. The deaths from diarrhœa, which had been 20 and 17 in the two preceding weeks, further declined during the week ending Dec. 23rd to 14, of which five occurred in Glasgow and three in Paisley. The fatal cases of whooping-cough showed a marked decline from the number in the preceding week and included five in Glasgow and three in Paisley. The deaths referred to different forms of "fever," which had been eight and six in the two preceding weeks, rose again during the week under notice to 10, of which five occurred in Glasgow. Of the eight fatal cases of scarlet fever five were recorded in Glasgow, where two of the three deaths from diphtheria were also registered. The 183 deaths referred to diseases of the respiratory organs in these towns slightly exceeded the number in the preceding week, and were 64 above the number in the corresponding period of last year. The causes of 37, or more than 5 per cent., of deaths in these eight towns during the week ending Dec 23rd were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 38 6, 38 5, and 38 2 per 1000 in the three preceding weeks, further rose to 42 5 during the week ending Dec. 23rd. During the past four weeks the death-rate in the city has averaged 39 5 per 1000, the rate during the same period being 23 9 in London and 18 3 in Edinburgh. The 285 deaths registered in Dublin during the week under notice were 29 in excess of the number in the preceding week, and included 38 which were referred to the principal zymotic diseases, against numbers decreasing from 72 to 34 in the five preceding weeks; of these, 24 resulted from measles, five from diarrhœa, three from diphtheria, three from "fever," two from whooping cough, and one from scarlet fever. These 38 deaths were equal to an annual rate of 5 7 per 1000, the zymotic death-rate during the same period being 2 3 in London and 1 0 in Edinburgh. The fatal cases of measles, which had been 30 and 23 in the two preceding weeks, rose again in the week ending Dec. 23rd to 24. The deaths from diarrhœa, which had been four and three in the two preceding weeks, rose again to five during the week under notice. The mortality both from diphtheria and from "fever" was slightly in excess over that in the preceding week. The two deaths from whooping-cough showed a decline from recent weekly numbers. The 285 deaths in Dublin during the week ending Dec. 23rd included 38 of infants under one year of age and 75 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Three inquest cases and seven deaths from violence were registered, and 97, or more than a third, of the deaths occurred in public institutions. The causes of 21, or more than 7 per cent., of the deaths in the city were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: O. B. Fairbank to the *Speedy*, when commissioned, and R. St. G. S. Bond to the *Pembroke*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel L. A. Irving, A M.S., is appointed Recruiting Medical Officer in the London Recruiting District, vice Lieutenant-Colonel W. Johnston, appointed for temporary duty at headquarters. Major Stuart assumes charge of the Station Hospital, Ahmedabad. Captain E. W. Cochrane is attached to the Station Hospital, Poona, for duty until further orders Major J. F Burke has arrived at York for duty. Major F. J. Morgan is appointed to the 7th Division, and Captain E. O. Anderson to the medical charge of the 1st Battalion the West Riding Regiment, for South Africa. Major F. J. Morgan has left for South Africa. Major Franklin, Major Cummins, Lieutenant Stafford, Lieutenant Davis, and Civil Surgeon Collum, have left in the *Goorkha* for South Africa.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the undermentioned officers are placed temporarily at the disposal of the Governments named:—Bombay: Captain D. C. Johnston and Captain F. A. Smith. Bengal: Captain W. D. Hayward and Captain A. W. R. Cochrane. Madras: Captain T. H. Foulkes and Captain C B Harrison Major J. T. W. Leslie (Bengal), Secretary to the Director-General Indian Medical Service, and Sanitary Commissioner with the Government of India, is granted furlough out of India for two years.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant D L. Hamilton resigns his commission. Surgeon-Lieutenant Colonel Francis James Pearse, 1st Middlesex Rifle Volunteer Corps, to be Surgeon-Lieutenant-Colonel. Surgeon-Captain R. B. Graham to be Surgeon-Major. Surgeon-Lieutenant Evan Evans, 1st Volunteer Battalion, the Welsh Regiment, to be Surgeon-Captain. Surgeon-Lieutenant William Owen Evans, 2nd Volunteer Battalion the Royal Welsh Fusiliers, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Devonshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant G. P. Barton to be Surgeon-Captain. 1st Sussex (Eastern Division, Royal Garrison Artillery): Surgeon-Lieutenant E. T. Cox to be Surgeon-Captain. *Rifle:* 3rd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant-Colonel W. H. G. Phelps to retire, with permission to retain his rank and to wear the uniform of the battalion on his retirement. 2nd Volunteer Battalion the Royal Sussex Regiment: Philip John Le Rich to be Surgeon-Lieutenant. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant E. Evans to be Surgeon-Captain. 3rd Volunteer Battalion the Essex Regiment: Hugh Neville Adam Taylor to be Surgeon-Lieutenant. 1st Volunteer Battalion the Royal North Lancashire Regiment: James Lea to be Surgeon-Lieutenant. 4th Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant D. L. Hamilton resigns his commission. 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Major J. H. Hay to be Surgeon-Colonel.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Lieutenant W. E. Miles to be Surgeon-Captain.

ARMY MEDICAL SCHOOL, NETLEY.

In consequence of the war in South Africa the following gentlemen, who were nominated by the Secretary of State for War as Surgeons-on-Probation in the Army Medical School, Netley, for the Royal Army Medical Corps, having passed an examination in the subjects taught in the Netley school, have been commissioned as Lieutenants in the Royal Army Medical Corps:—

A. H. Safford.
A. F. Carlyon.
C. R. Evans.
C. S. Cato.
J. A. Hartigan.
H. C. R. Hine.
J. F. Martin.
J. M. Buist.
G. H. Merry.
W. C. Croly.
E. McDonnell.
A. MacLoughlin.
A. J. M. Cuddon-Fletcher.
R. L. Davies.
C. S. Smith.
C. C. Cumming.

MENTIONED IN DESPATCHES.

In a despatch to the Secretary of State for the Colonies signed by Colonel F. D. Lugard, C.B., D.S.O., relative to the West Africa Field Force operations, the following paragraph occurs:—"I noticed that the published list of rewards contained no recognition of the excellent services of the Medical Department, of whose work I spoke in my despatch in the strongest terms at my command. I venture to bring to special notice the name of Dr. W. Poole, Principal Medical Officer of the Force, whose previous record of service in Nyassaland under the Foreign Office constitutes an additional claim upon Government."

In a despatch from Colonel Ternan, D.S.O., to the Secretary of State for Foreign Affairs the name of Captain Haig, I.M.S., is mentioned with reference to services in the operations against Kabarega, late King of Unyoro.

TRANSVAAL WAR NOTES.

The entire medical equipment of the City of London Imperial Volunteers throughout the present war in South Africa is being supplied as a gift to the nation by Messrs. Burroughs, Wellcome, and Co.

Following the practical sympathy shown by the medical men at Newport in placing their services at the disposal of reservists' and militiamen's families, the governors of the Newport and Monmouthshire Hospital have resolved to honour all prescriptions granted by the medical practitioners who are attending the families at their homes.

Sir William Thomson, ex-President of the Royal College of Surgeons in Ireland, has been appointed chief surgeon to a special Irish base hospital which is being equipped by Lord Iveagh. Sir William Thomson will be assisted by four surgeons and the hospital will be stationed on the lines of communication at the places where it may be most urgently required on its arrival in South Africa.

A telegram from the *Times* correspondent at Marques, dated Jan. 2nd, states that "Major Daly's ambulance corps ...... left Dundee for Pretoria on Sunday with 29 wounded. The Boers gave the doctor to understand that he would be allowed to attend the wounded at Pretoria, but he was not even permitted to take them off the train and see them lodged in the hospital, although several cases were critical. ... The Boer authorities at Dundee behaved shockingly towards the British ambulance, notwithstanding the kindness shown to the burgher wounded. For 11 days the doctor and his men were kept strict prisoners in a compound. During Christmas there was a terrible amount of drunkenness and rowdiness in the town, the Boers going about with loaded Mausers. One twice pointed his rifle at the doctor."

We understand that Dr. Conan Doyle will shortly leave for South Africa in connexion with a stationary hospital.

We understand that the War Office is endeavouring to ascertain how many beds each of the large hospitals in this country will be able to place at its disposal in case of need.

Major Burtchaell, R.A M.C., who was made prisoner by the Boers at Magersfontein, has, we understand, been released.

DEATHS IN THE SERVICES.

The *Times* announces the death of Surgeon-Major Alexander Gibb Grant, Bengal Army, Hon. Surgeon to the Queen, retired, on Jan. 3rd, at his residence in Connaught-square, Hyde-park.

In future an officer serving in India who has received in action a bodily injury certified by the regulated medical authority to be very severe, though not equivalent to the loss of a limb, will be allowed a gratuity of from three to 12 months' full pay of the appointment held by him at the time of the injury.

Correspondence.

"Audi alteram partem."

AN APPEAL TO THE YOUNGER MEMBERS OF THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—In the crisis through which our Empire is passing the importance of the Militia, Yeomanry, and Volunteer forces as a support to the army is fully evinced. And as it is impossible to forecast the further demands which may have to be made upon them in the near or distant future it behoves us to strengthen them to the utmost of our power.

Many members and students of our profession are already enrolled in them and are answering the call now made upon them with patriotic promptitude. We venture to take the opportunity suggested by the beginning of a New Year of appealing to such of the younger members and of the students of the medical and dental professions as are still unattached, yet capable of bearing arms or in other ways of helping in Imperial defence, at once to consider the advisability of joining some branch of the service.

FREDERICK T. ROBERTS, M.D., F.R.C.P. Lond.,
Physician to University College Hospital;
EDMUND OWEN, M.B. Lond., F.R.C.S. Eng.,
Surgeon to St. Mary's Hospital;
WILLIAM COLLINGRIDGE, M.A., M.D. Cantab.,
Surgeon-Lieutenant-Colonel Militia Medical Staff; late commanding Militia Medical Staff;
WILLIAM DUNCAN, M.D. Brux., F.R.C.S. Eng.,
Captain Middlesex Yeomanry Cavalry;
J. EDWARD SQUIRE, M.D., M.R.C.P. Lond.,
M.R.C.S. Eng.,
Surgeon-Lieutenant-Colonel Commanding Volunteer Medical Staff Corps (London Companies).

London, Jan. 1st, 1900.

"DENTAL APPOINTMENTS AT GENERAL HOSPITALS."

To the Editors of THE LANCET.

SIRS,—As you have kindly opened your pages to a correspondence on the qualifications of dental surgeons to general hospitals, I hope that the question may not be complicated by considering the case of hospitals having dental schools attached to them or the qualifications required by teachers in purely dental hospitals. The point for the medical profession to consider is the advantage accruing to the general students or to the general practitioners who may require dental instruction during their hospital studies or after they have secured their diplomas. Unless the character of medical students has greatly changed I do not think that they are likely to seek or to receive information very graciously from gentlemen, however competent, who from their (the students') point of view occupy a professional position so different from their own. Again, a dentist who has taken the additional qualifications is able to take a surgical or medical as well as a purely dental view of the subject either in lecturing or in operating. That the general student requires special instruction in matters dental is often painfully obvious to all educated dentists who have to meet general practitioners professionally and it is not always easy to do what is right for the patient and at the same time cover the position assumed by the medical adviser. For these and many other reasons I think it very desirable that the dental surgeon to a hospital to which a medical school is attached ought to carry both the diplomas of the dental surgeon and of the general practitioner. I also believe the idea that all dental surgeons will one day have the double qualification to be Utopian, and if realised would be injurious to the best interests of the general public so far as dentistry is concerned.

I am, Sirs, yours faithfully,

George street, Hanover square, W. JAS. SMITH TURNER.

To the Editors of THE LANCET.

SIRS,—May I be allowed to supplement your very excellent annotation in THE LANCET of Dec. 23rd, 1899, upon this subject?

For many years *all* the London hospitals having medical schools attached required that their dental surgeons should in addition to the licence in dental surgery possess a surgical qualification. Several years ago two of them decided to abolish this rule and required only the L.D.S. diploma for their dental surgeoncy. The authorities of one hospital at the same time relegated their dental surgeon to a similar position to the dispensers of the hospital—that is to say, they were no longer to be treated as members of the staff, they were deprived of their seat on the medical committee, they had no voice in the management of the hospital or school, they had no share in the profits of the school, nor were they constituted paid officials, the sole recompense for their rather laborious services being that their names appeared as members of the staff. I believe I am right in saying they were the only truly honorary members of the staff. If the L.D.S. only was to qualify them for the position why were they to be subjected to the indignity of being placed in an inferior position to any other member of the staff? The charity in question appears to convict itself of inconsistency.

I venture to protest against this invidious distinction and to urge the authorities to go back to the old regulations and restore to their dental surgeon the privileges of which he has been deprived and to require such qualifications as may ensure his receiving the same courtesy from the staff, the students, and the committee of management as is accorded to those in charge of every other special department of a hospital; but this cannot be so if the L.D.S. only is to be a sufficient qualification for the appointment, because the curriculum for that diploma is fragmentary in medicine and surgery and the examination in those subjects and in anatomy, physiology, pathology, therapeutics, &c., is not adequate to place the holder of that diploma on an equal position with the other members of the staff. The dentist should rank equally with other members of the staff, and therefore his name should be found upon both the Dental and Medical Registers which is a guarantee that he possesses the knowledge and has had the education to efficiently equip him to teach medical students. That a dentist's opinions and vote are of value and often of importance is instanced in the discussions at the General Medical Council, where Mr. Tomes, a dental representative, has, in addition to the services rendered on dental matters, also taken a very active, honourable, and important part in questions relating to medical and surgical matters that have been under consideration.

I am, Sirs, your obedient servant,

MORTON SMALE.

The Dental Hospital of London, Jan. 1st, 1900.

"THE CONFERENCE AT NEWCASTLE AND THE MIDWIFERY QUESTION."

To the Editors of THE LANCET.

SIRS,—IN your issue of Dec. 23rd, "A Physician" has boldly elected to wrestle with the vexed midwifery question, though, in truth, he has not been brave enough to sign his name. He has gripped the subject by the throat in a very *determined* manner with all the force of first, second, and third seizures.

I have looked through his letter carefully and slowly, and after running my pen through lines that everyone is familiar with, and cancelling others that are scarcely germane, I find myself left with the following sentences: "All are agreed, Parliament and profession, that there is somewhat requiring remedy. That is where we are now. A remedy is to be devised. More, a remedy is going to be devised and enforced. Those who object to all and every remedy misconceive the position. It is no longer a question of what does the profession want or not want, it is which way is the inevitable remedy to be devised and applied? The Houses of Parliament know that well enough. The General Medical Council knows it well enough. Mr. Victor Horsley, as plainly appears by his speech on the subject at Newcastle, knows it well enough. The strange thing is that a considerable section of the profession does not seem to know it," and *so on*.

Now, these very sentences show, following as they do a reiterated preamble, that the writer of them is just about as helpless in the face of the midwives question as an average country parson is over incense. The mere shrieking "We must do something" in the centre of a grass-grown arena amounts to energetically doing nothing, after all, beyond clearly proclaiming helplessness. Therefore I deem three-fourths of the effort which he has made in his letter to be absolutely useless. I should have been better pleased to see him turn up his sleeves for real battle in the first half-dozen lines I should have liked to see him draw blood somewhere in the first half column by the home thrust of some convincing and clean-cut argument. No; the letter of "A Physician" will not tend in any way to help us in our troubles. I cannot avoid the suggestion of dual object which it gives me when I look again over the lines of it. I ask myself: Why has this letter been written? Has it a policy? Is its purport quite clear on the face of it? Is it signed by the medico's name? Still, in all charity, I go on searching and at last I find something—a remedy, "just as was done in the plumber's case." Your correspondent advocates registration of midwives and nothing more, and he points out a few advantages which would follow.

Now, who is there to find fault with registration? No one in their right senses. Registration is good; I myself strongly advocate it, but registration of what? I repeat the gist of my advocation as set forth and published in 1897 in "Economics, &c., in the Practice of Midwifery"—that midwives as formerly and at present understood should be abolished. Even the name should go. I would have in their place a new body of registered obstetric nurses, properly trained, whose powers and procedures should be strictly limited and who should be supervised at some stage in every case of confinement, no matter where occurring, by a qualified medical attendant who should see each case at least once during or after delivery. What time a nurse should send for a medical attendant should be left to her instructed and schooled judgment. She may deem it wise to send during labour; and she would always be likely to send soon enough, knowing that she was bound to send sooner or later. Thus no case of labour should escape at least a single inspection of a qualified medical attendant—even those living in remote districts, whose lives are as precious as any others Hence would follow order, discipline, and right practice.

I could not in the space of a letter deal with the innumerable points concerning practicability which a whole scheme involves, but I am prepared to tease out any knotty point or to suggest plans to meet whatever difficult situation should appear to correspondents in THE LANCET who should desire to find fault with my principles as I enunciate them. I would only ask for short and clear objections or arguments or criticisms and I will promise to deal with them as shortly, for the whole subject is a large one.

I am, Sirs, yours faithfully,

HAYDN BROWN.

London, Dec. 31st, 1899.

of saturation, and the report therefore states that the rules so determined should not be superseded by the necessarily limited experience of any local authorities.

There appears to have been no evidence of earthquake as at first reported. Local tremors, however, may have been felt as the result of the heavy landslips. The excessive fall of rain at the final stage of a severe cyclone and at the end of the rainy season is sufficient to account also for the simultaneous occurrence of the large number of landslips in and near Darjeeling. The other contributory causes are reported to be "defective site drainage, excessive lead of road drains, imperfectly or badly constructed revetments, neglect to reduce or protect steep slopes, and undercutting steep slopes for the formation of paths, roads, and outhouses." The committee recommend the following measures to be taken to minimise the chances of future damage. Better drainage, especially of roads along slopes, a special preparation of sites for dwellings, treatment of ravines and springs, reduction of slopes above and below house sites to an inclination not exceeding 37 degrees, the planting of trees, and the improvement of revetments. In addition the committee recommend certain prohibitions concerning quarrying, cutting paths, roads, and sites for buildings, and other works. The importance of Darjeeling as a hill station for Calcutta has demanded this searching inquiry, and it is estimated that at least one and a half lakhs of rupees will be required to repair damages and to carry out the necessary protective works.

While the plague has been abating during the past few weeks larger and larger areas have been suffering from famine. In Bombay city the mortality from plague has only slightly risen, but the general mortality has gone up with great rapidity and this increase forebodes ill. In Calcutta also the general mortality is decidedly above the average and there were more deaths returned from plague.

The futility of laymen reporting upon medical matters has been pointed out over and over again, and the following extract from a recent circular sent to civil surgeons and others under Government authority is noticeable. The author writes on the "Rôle of Rats" in plague, and says, "It is by feeding on the residual matter in the excrement of plague-infected persons that rats acquire the disease; they then transmit it to one another. From rats it is conveyed to human beings by articles of food such as ghee, oil, sugar, milk, butter, &c. Plague is transmissible through the air or by personal contact." It is said that this document is being circulated by the Government to all civil surgeons "for information." I trust that this is a mistake and that it is only confined to the Hyderabad State, from which it appears to emanate. I should also like to express a hope that the Sanitary Commissioner has not sanctioned its circulation.

Dec. 14th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary and Sick and Wounded Soldiers: A Patriotic Offer.

THE committee of the Royal Infirmary are desirous of assisting the War Office authorities in the pressure of hospital accommodation experienced during the present crisis. They have offered to place 12 or more beds at the disposal of that department for sick and wounded soldiers invalided from South Africa who may belong to the Liverpool district. The example which has been set by Liverpool's premier charity has, I understand, already borne fruit, one or more of the other local general hospitals having decided to assist the Government in a similar manner.

Proposed Legislation by the City Council for the Prevention of Tuberculosis from the Milk-supply.

The City Council are promoting an Act in the next session of Parliament by which powers are sought for dealing with the milk-supply in Liverpool with reference to the suspected presence of tuberculosis. If on analysing a sample of milk taken from any city shippon the tubercle bacillus is discovered, the medical officer of health is to be empowered to have the cows milked under inspection and to have separate samples analysed. On the detection of the consumptive cows the owner is required under penalty by the Act to isolate them, and is prohibited under a penalty not exceeding £10 from selling any milk taken from such cows. With reference to the milk coming from country dairies, if the tubercle bacillus is detected in milk sampled at a railway-station or from a cart in the street, or at a milk-dealer's, the medical officer of health, on discovering the dairy from which this milk has been sent out, may apply to, and obtain an order from, a justice of the peace in the district where the dairy is situated and under such order may have the cows milked under inspection. If any cows are found to be infected the medical officer may obtain an order from a city justice prohibiting the sale within the city of milk coming from that dairy until such time as he is satisfied that the danger of infection has passed away. The penalty for an infringement of the Act is £10. On production of satisfactory proof that his cattle are free from tuberculous disease the cowkeeper or farmer may himself apply to have the order rescinded. Another clause in the Act imposes a fine not exceeding 40*s*. on cowkeepers within the city for failing to notify cases of tuberculosis. It will be impossible to enforce this clause in the Act unless it can be proved that the owner of the cow or cows was aware of the presence of tuberculosis in the animal. In its early stage, when no external symptoms present themselves, the owner has no means of detecting its presence.

The Rating of Liverpool Charities.

The Finance Committee of the City Council have decided to inform the managers of the various hospitals and charitable institutions in the city that they are unable to exempt hospitals from the payment of rates. They are, however, prepared to receive the rates on whatever assessment may be placed on the properties by the Poor-law authorities. The hospitals have hitherto been assessed by the magistrates at *nil*.

The late Dr. Robert Robertson.

It was with sincere regret that the medical profession of Liverpool received the intelligence of the death of Dr. Robert Robertson on Dec. 22nd, 1899, after a very short illness. Dr. Robertson graduated as M.D. in the University of Edinburgh in 1863. In 1865 he was appointed a resident medical officer at the Liverpool Workhouse, to which he was subsequently appointed physician upon the retirement, in 1891, of the late Dr. Robert Gee. He was also physician to the Netherfield-road Fever Hospital and to the Liverpool Consumption Hospital, in all of which posts his services were held in the highest esteem. Sympathetic allusions to the late Dr. Robertson were made by Mr. William Rathbone and others at the recent meeting of the Select Vestry, by whom his services were highly valued.

Liverpool Workhouse Hospital.

For the post of physician to the workhouse hospital rendered vacant by the death of Dr. Robert Robertson some excellent candidates are in the field. Besides being a lucrative appointment, the post is a very valuable one from a clinical point of view. The opportunities which it affords for research work are exceptionally great owing to the large number of cases admitted to the wards. There is a strong feeling in the profession that the appointment should be given to the fittest candidate, in fact to one who could make use of the extensive field for work available at the hospital It would be a great misfortune if creed or political influences should debar a first-class candidate from obtaining the desirable post.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary: Annual Report.

THE annual report of the managers of the Edinburgh Royal Infirmary to the committee of contributors states that 9694 patients were treated in the wards during the year—an increase of 260 on the number in the previous year. In the out-patient department 29,439 patients had been treated, this being an increase of 610 as compared with last year. The ordinary receipts, which amounted to £30,739 10*s*. 7*d*., showed an increase of £355 10*s*. 11*d*. over the returns for the previous year. In voluntary contributions there was an increase of £510 1*s*. 9*d*. The ordinary expenditure amounted to £43,882 3*s*. 11*d*., being a

Table showing the Number of Students from various Medical Schools who have obtained the Degrees of M B B Ch, and B A O (equivalent to the M D of the Queen's) in the years 1889, 1894 and 1899

[illegible]	1889	1894	1899	Total for three years
Queen's College, Belfast	32	21	27	80
Queen's College Cork	15	8	11	34
Queen's College, Galway	2	—	1	3
Catholic University Medical School	6	5	10	21
School of Physic Trinity College	5	1	—	6
Royal College of Surgeons in Ireland	—	1	—	1
London School of Medicine for Women	—	1	—	1
Durham University	—	1	—	1
Mixed returns	10	—	2	12
	70	32	51	159

These statistics show that all the Queen's Colleges have been impaired in their usefulness by the establishment of the Royal University of Ireland The arts faculty in Cork has been ruined and in Galway it has diminished one half, and the medical faculty in Cork is about half what it was while in Galway it is destroyed Further, these figures, Dr McKeown contends, show that both in arts and medicine the Catholic University College, Dublin, and Catholic University Medical School, notwithstanding their predominant position and influence, have failed to show the return of graduates which surely was expected by the Government in establishing the Royal University of Ireland In fact, from that point of view, the Royal University of Ireland has been a failure But, further, these figures demonstrate that in the arts faculty the great majority of students graduating in the Royal University of Ireland have studied in colleges or schools not associated with the university, or have studied privately, for in the three years tabulated no less than 252 out of a total of 420 who took the degree of B A did not study in any of the colleges associated with the university Many of these colleges and schools have been brought into existence or have been given a great impetus by the Royal University of Ireland, and some have come out most creditably both in the honour and pass lists Queen's College Belfast, has suffered in both the arts and medical faculty by the establishment of the Royal University of Ireland The injury to the arts school is not due, as it is in the medical faculty, to the constitution of the board of examiners and the unfair influence (in the relative number of examiners) of one Dublin school, but mainly owing to the opening of the arts degree to all comers without obligatory attendance on lectures The students graduating in arts from "private study" and from "other colleges and schools" in the Royal University of Ireland are one and a half times as numerous as those from all the privileged colleges put together The Queen's Colleges founded by the Government have been starved by the Government The chairs are not properly endowed, and no provision is made for assistant professors or for tutors The very fact that the colleges are Government institutions and controlled far too much in the past by subordinates in Dublin who delight in religious and political intrigue, have prevented the people in their vicinity endowing them as they would, had they been in the position of the University of Edinburgh or the University of Glasgow Dr McKeown suggests another in addition to the many plans previously put forward to settle this most difficult question His method may be styled, "Local Government of the Queen's Colleges" He advises that the governing bodies of the Queen's Colleges should be made as far as possible representative, and that they should be properly endowed, cut off from Government interference in their management and made local The North of Ireland would have a board to please itself, the West and South the same In this way the people of the districts in which the colleges are located would take a real interest in them The governing board might contain representatives of the teachers and of the graduates, official representatives of some public bodies and eminent persons in thorough sympathy with the colleges Were the colleges in the position in which they ought to be—local, democratic, and endowed, Dr McKeown thinks that then a re-organisation of the Royal University of Ireland after the manner of the University of London, might be seriously entertained. Whether Dr. McKeown's plan will "catch on" or not, one thing is clear to everyone, that nothing could be more unsatisfactory than the present condition of college and university education in Ireland The man who would solve such a question would indeed confer a lasting benefit on Ireland and be a true patriot.

Influenza [illegible]

For the past few weeks cases of mild influenza have occurred in Belfast, but since Christmas it has assumed a widespread epidemic form and the type of the disease is distinctly worse than in the influenza which prevailed last year Pulmonary complications are met with most frequently and the death rate in elderly patients has been very high The weather, too, has been most trying, days of frost being immediately followed by the mildest spring like weather

Death of a Medical Man from Accidental Poisoning

Mr William J Belcher, for many years the medical officer to the Union Hospital, Bandon, co Cork, was poisoned on Dec 30th by a dose of dilute carbolic acid which he accidentally swallowed in mistake for a draught of fluid magnesia Although the accident occurred at 1 o'clock in the day, and although skilled medical assistance was summoned with the utmost possible despatch, death had taken place before Dr Reid arrived It would seem that nowadays, and in these countries, carbolic acid is by far the most frequent and fatal of poisons.

Operations on Lunatic Patients in Asylums

THIS very grave question has been under discussion at the Society of Legal Medicine, the subject having been introduced some six months ago in an important paper by M Picqué and M Briand They came to the conclusion that the surgeon should only interfere in cases of absolute urgency M Leredu, a barrister, sent in a report to the society on the question formulated as follows —"Is a surgeon within his rights in performing a surgical operation upon a lunatic without the consent of the patient's relatives?" He answered in the negative, except in a case of absolute urgency A lunatic is unable to give consent it is his relatives who must give consent to the operation But the relatives may refuse consent, possibly from fear of an unsuccessful result, or on the other hand, with the deliberate wish to deprive a person who is a disgrace and expense to them of a chance of life Again, the relatives may not choose to answer, or the lunatic may have no relatives It is, then, the legislature that must be asked to supply an answer to the question It would be easy to settle it by an enactment drawn in some such terms as these "When a surgeon is of opinion that surgical interference is called for in the case of a person who is an inmate of a lunatic asylum he shall obtain leave to operate from the relatives of the patient In case the relatives refuse the director of the asylum shall at once inform the Procureur of the Republic This official shall put the tribunal in possession of the facts whereupon it may rule the case to be one of urgency and the proposed operation to be a last resource, making the order in the Chambre de Conseil, after having referred the matter, should it think fit, to medico-legal experts for an opinion as to the propriety of surgical intervention M. Picqué, in supporting the opinion of M Leredu, showed how difficult it was to obtain a really valid consent from relatives In 20 cases where he applied for leave he received but one answer The disagreeable consequences (which may arise to a surgeon through operating without consent being taken for granted M Picqué would only dispense with such consent in the three following instances suffocation, strangulated hernia and arterial hæmorrhage There might be others, such as metrorrhagia and conditions associated with the urinary organs, but so long as the matter was not settled, either by statute or by a resolution of the society, he would not interfere, unless he had some authorisation in writing, for fear of incurring both moral and material responsibilities which in France were very grave If the patient were to die his relatives, who had shown themselves absolutely indifferent when permission was asked of them, would not hesitate to claim damages and to attack the surgeon in the public prints Even if the operation were successful the surgeon would not be free from the risk of disagreeable consequences In the discussion which followed without any conclusion being then arrived at, it was curious to see the legal members, among whom was M [illegible], the Advocate General giving the opinion that it was right for the surgeon to operate if he th [illegible] against the wishes of the relatives, while the medical members were less bold and demanded some legal protection to cover their responsibility. As a matter of fact, despite the philanthropic and philosophic views of individual members of the magistracy, the medical profession know only too well how of late these very magistrates have, when sitting in court, shown themselves both severe and unfair towards medical men and how ready they are to entertain complaints from the relatives of patients against their medical advisers.

Spitting on the Pavement.

The Sixth Committee of the Municipal Council of Paris has recently had under consideration a proposal laid before it by M. Fortin, a member of the council, suggesting that the populace of Paris should not spit on the footways. The practice is already prohibited in omnibuses, railway-stations, and certain public places. The committee decided, after some discussion, to put up enamelled metal notices, sufficiently large to be read at some distance, in the chief streets and public buildings, bearing the following inscription: "The public are requested, in their own interests and with a view to avoid disseminating infectious diseases, to abstain from spitting on the pavement."

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Statistics of the Medical Profession.

ACCORDING to Börner's Medical Directory, edited by Dr. Schwalbe, the number of medical men in Germany is 26,689. The *Deutsche Medicinische Wochenschrift* states that since the previous enumeration there has been an increase of 932—i.e., 3·6 per cent. Of these medical men 16,103 reside in Prussia, 2947 in Bavaria, 1968 in Saxony, 870 in Würtemberg, 1027 in Baden, 661 in Hesse, 766 in Alsace-Lorraine, and the remainder in the other states of the confederation. During the last 11 years the medical profession has increased 56 per cent., whereas the number of the population has increased only 14 per cent. In 1887 there was one medical man for 3000 persons, but in 1898 there was one for 2197 persons. The most considerable increase during the last 11 years was in the medical officers to hospitals, clinics, laboratories, &c., their number having risen from 581 to 1924, an increase of 232 per cent., whilst the general practitioners increased 52 per cent. and the army and navy medical officers 21 per cent. It is remarkable that in 1887 as many as 57 per cent. of the army and navy medical officers were engaged in civilian practice, but in 1898 only 31 per cent. With regard to the geographical distribution of the profession it is stated that the eastern districts have far fewer medical men than the southern and western districts. Berlin has of course the greatest number of medical men—viz., 2233; Munich, 637; Hamburg, 533; Breslau, 510; Leipsic, 411; Dresden, 408; Cologne, 332; Frankfort, 312; Charlottenburg, 298; Königsberg, 250; Hanover, 234; and Strassburg, 234. Of the Berlin medical men two were qualified in 1842, two in 1843, and four in 1844. More than 46 per cent. of the Berlin members of the profession became qualified during the last ten years.

The Institution for Infectious Diseases.

Professor Brieger, the head of the clinical department of the Institution for Infectious Diseases, is resigning this appointment to become professor of general therapy at the University of Berlin. The chair of General Therapy has been created recently; the *Deutsche Medicinische Wochenschrift* rightly observes that theoretical lectures on therapy are not of great value and that the professor of general therapy ought to have wards where he might demonstrate the different methods of treatment. In addition to losing Professor Brieger the staff of the Institution for Infectious Diseases will undergo considerable alterations: Dr. Marx is going to Frankfort, where he has received an appointment at the Institution for Experimental Therapy under Professor Ehrlich; Professor Pfeiffer, the head of the laboratory department, has been promoted to be professor of hygiene at Königsberg. The places of Professor Brieger and Professor Pfeiffer will be taken by Professor Dönitz and Professor Frosch, the German commissioners for the investigation of the plague in Portugal. Professor Koch, who is at the head of the Institute, is still in the Dutch Indies prosecuting studies on malaria.

Actinomycosis of the Kidney.

A very rare specimen was recently shown to the Berlin Medical Society by Professor Israel. It was the kidney of an army officer who in 1892, without any obvious cause, was seized with hæmaturia and severe pain in the region. In 1894 a surgeon performed nephrotomy on the supposition of the presence of a renal calculus. The kidney proved to be normal, no calculus was detected, but there were firm adhesions to the surrounding parts so that the kidney had to remain *in situ* and was not brought through the wound for inspection. The wound healed without complication, but the urine became opaque and contained blood, the patient had night sweats, and his weight decreased considerably. In 1898 a fistula formed and discharged a small quantity of sero-purulent fluid. In August the fistula was incised without any improvement resulting. Not long ago the patient came under the care of Professor Israel. He was very weak, there were several fistulæ at the old cicatrix discharging pus with granules which proved to be actinomyces, and actinomyces was present in the sediment of the urine. By cystoscopy the mucous membrane of the bladder was found to be normal. Nephrectomy was therefore performed. The lower part of the kidney did not show any alterations; in the upper part there was a yellow tumour consisting of fat with actinomyces; growths of the same kind were also present between the capsule and the kidney. In the pelvis of the kidney there was a calculus consisting of masses of calcified actinomyces. This is the first case of operation for actinomycosis of the kidney.

Midwives in Berlin.

The midwives of Berlin are very strictly controlled by the medical officers to the Berlin police. Not long ago a qualified midwife was prosecuted and fined because she had contradicted a medical man in presence of a parturient woman, this being regarded as a misdemeanour because the patient was thereby induced to believe that the medical man in charge was incompetent. The medical department of the Berlin Police has also issued an order to the qualified midwives informing them that it is illegal to recommend individual medical practitioners to women in their confinements, because a law passed in 1725 provides that the patient must be at full liberty to consult any medical man she desires. It is especially against the law for midwives to have an agreement with a medical man and to be paid by him for recommendations to patients.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Hygiene and the Holy Year.

IN view of the masses of pilgrims who will be quartered in Rome at frequent intervals during the Holy Year the Minister of Foreign Affairs (the Marchese Visconti Venosta) has instructed the Italian consular service throughout the two hemispheres to supply the Government with full and accurate reports as to the sanitary condition of the several countries whence the pilgrimages in question are preparing to start. This is quite a necessary precaution. The central authority is making every effort to obviate the overcrowding anticipated from the influx of so many "caravans" of the faithful. But even before their accommodation in conventual establishments and provisional "baracche" (barracks) becomes a practical question the Government must have satisfactory assurance that they will not import the germs of infective maladies from their several "places of origin" or "points of departure."

Dr. Mazzoni and the Ceremony of the Porta Santa.

The solemn inauguration of the Holy Year on Christmas Eve was not without its amusing episodes, prominent among them being that of which Dr. Mazzoni was the hero. His presence at the august ceremony was only less *de rigueur* than that of Dr. Lapponi, but owing to urgent professional engagements he was late in presenting himself. Still worse, he had forgotten to come fortified with the indispensable "biglietto d'ingresso" (ticket of admission). Arrived at the bronze door leading to the Pontifical apartments he was met with the inexorable demand, "Biglietto, signore, biglietto." Hardly hearing or attending to the reminder, Dr. Mazzoni in his haste was pressing on and in four "leaps or bounds" would have been ascending the staircase, when a heavy hand laid on his shoulder gave him pause and the same voice, rather more sternly, repeated the question, "Fostro biglietto? Foi non capite?" (Your ticket? Don't you understand?) It was the stalwart Swiss Guard whose speech bewrayed him in the accents of Solothurn or Freiburg. Dr. Mazzoni, eager to be in time, could only protest, "Ma che biglietto? Io non ne ho bisogno." (But why a ticket? I don't need one.) "Fostro biglietto! Nessuno passa senza biglietto!" (Your ticket! No one gets through without a ticket) insisted the Guard. "Ma sapéte chi sono?" (But do you know who I am?), rejoined Dr. Mazzoni. "Neppure il nipote del Papa passa senza biglietto. *Date dietro!*" (Not even the Pope's nephew passes in without a ticket. Keep back!) was the reply of the "invisus janitor," who was just about to point his halberd at the medical man's breast when a high functionary of the Vatican came up and ended the altercation. The "Cerbero Elvetico" (Swiss Cerberus) had to bow to "force majeure" and permit the surgeon who in March last had saved the Holy Father's life to pass on and reinforce his colleague, Dr. Lapponi, as a specially interested "assessor" at the proceedings.

The Crusade against Malaria.

Is the sufferer from malaria a source of danger to his healthy neighbours? The question came before the last meeting (on Dec. 27th) of the Società Piemontese d'Igiene and was answered in the affirmative by Dr. Pio Foà, professor of pathological anatomy in the University of Turin. On the strength of recent discoveries, checked by still later experience, Professor Foà maintained that malaria could be indirectly communicated, and his view, strongly supported by the president of the society, Dr. Luigi Pagliani, professor of hygiene in the same university, was unanimously approved by the meeting. There is thus, according to Professor Foà, a fresh prophylactic reason for curing malarious subject, and accordingly he proposed an "order of the day" by which the Government was invited to make provision for the sale of quinine to the fever-stricken poor at cost price. Professor Pagliani, in seconding the proposal, which was ultimately carried, was of opinion that the Società d'Igiene, as it had already interested itself in the various methods devised to combat tuberculosis, should also assume a similar attitude towards malaria and invite the profession and the Congregazioni di Carità to join in the movement indicated So far so good, but to the proposal for the cheap supply of quinine a *caveat* was added protecting the interest of the pharmaceutical profession—and this was better.

Re-appearance of the Plague at San Paulo.

From a telegraphic message received at Genoa and dated "Rio Janeiro, 28th inst.," I learn that the pestis bubonica which was thought to have disappeared from San Paulo and its neighbourhood has returned in greater force than ever. Three very marked cases were reported on the 27th and, what is worse, they were found by the physicians to partake of the pulmonary form of the disease, which is not only the most uniformly fatal but also that which is most contagious. In these cases the sputum is always a source of danger, and still more the profuse, watery, often "sanguinolent," exudation, literally swarming with bacilli As soon as the central authority was advised of this renewed outbreak, the requisite sanitary precautions previously in force were vigorously resumed, no effort being spared to localise the disease. The panic at San Paulo is, of course, immense, but the prompt action of the Government is already restoring calm. At Santos the situation continues unchanged. For 15 days the whole region has been free from the disease.

Dec 31st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases in Austria.

THE official statistics of the morbidity and mortality due to infectious diseases in Austria in the year 1898 have just been published. No less than 8674 cases of small-pox with 1594 deaths were recorded. The majority of these cases occurred in the eastern provinces, where the population is least intelligent and where vaccination cannot be carried out as efficiently as in the western provinces. Of the number just quoted 6996 cases (with 1228 deaths) occurred in Galicia and 1627 cases (with 363 deaths) in the Bukowina. In the two districts of Klinaentz and Tontina Alba 335 cases of small-pox occurred among children and four among the adults; of all the patients only two had been vaccinated, but the majority of the adults in these two districts showed small-pox scars as in a population of 2306 adults 1532 persons were found to be marked with small-pox. During 1898 there were also recorded 15,344 cases of scarlet fever (with 9651 deaths), 198,435 cases of measles (with 9179 deaths); 24,131 cases of typhoid fever (with 3544 deaths); 4147 cases of typhus exanthematicus (with 362 deaths); 6318 cases of dysentery (with 1266 deaths); 1566 cases of puerperal fever (with 846 deaths), and 32,296 cases of diphtheria (with 9095 deaths). Of these cases of diphtheria 15,333 were treated with serum injections and of that number only 2428 died, giving a mortality of 15 89 per cent; whilst among 16,963 cases treated without serum 6667, or 39 30 per cent., succumbed. These figures seem to be in favour of the serum treatment in diphtheria.

Plague on an Austrian Steamer.

The Austrian Lloyd steamer *Berenice*, which recently arrived with a cargo of coffee from Brazil at Trieste, was infected with plague in a Brazilian harbour and four cases of plague occurred on board during the voyage. As the cargo represented a value of more than 2,000,000 florins the opinions of sanitarians and of the public were divided as to the precautions which should be taken under the circumstances. The ship was taken to the Trieste quarantine station and all on board were conveyed to the Trieste Lazaretto for infectious diseases, where they are isolated and will remain for a fortnight. It has not yet been decided whether the coffee will be thrown into the sea, as is demanded by the majority of the public in the fear that the infection of plague will be dispersed throughout the country by selling it, or whether it will be transferred to new bags, or whether it will be sufficient to treat the bags with a disinfectant before sending the coffee to the market. Some medical authorities have recommended the strongest measures, while others seem to be content with less destructive procedures which would not entail the loss of these 2,000,000 florins.

New Rules for Examinations in Medicine.

Within the next few days the new rules for the qualifying examinations in medicine will be issued. The principal changes will be that the so-called preliminary examinations in zoology, botany, and mineralogy will be abandoned. The first examination will include biology, anatomy, physiology, natural philosophy, chemistry, and histology. Mental diseases, diseases of the ear, hygiene, and dermatology have now been added to the list of subjects comprised in the two final examinations

Births, Marriages, and Deaths.

BIRTHS

ROBINSON.—On Dec. 29th, at The Villa, Harleston, Norfolk, the wife of J. C. Reynolds Robinson, M.R.C.S., L.R.C.P., of a son.

RUTHERFURD.—On Dec. 30th, at 12, Newton-place, Glasgow, the wife of Henry Rutherfurd, M.B., of a daughter.

MARRIAGES

NASH—OLDERSHAW.—On Dec. 28th, at St. Alban's, Acton-green, Edwin H. T. Nash, M.R.C.S., L.R.C.P., of Oakhell Houses, Accrington, to Mary Monica, only daughter of Walter Oldershaw, of Blandford-road, Bedford-park.

DEATHS

HARRISON.—On Dec. 30th, at Holland Lodge, Clifton, Bristol, Selina, the beloved wife of Alf. Jas. Harrison, M.D., J.P., aged 69 years.

HOWISON.—On Dec. 23rd, James Howison, L.R.C.P., L.R.C.S., L.M. Edin., of 31, Abbey-road, London, N.W. (late of Darlington), in his [illegible]th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE COURAGE OF IGNORANCE.

BEFORE the coroner at Devizes recently an investigation was held into the cause of the death of a servant girl when evidence was given of obstinacy on the part of the deceased which medical men are well aware is commonly displayed by servant girls and which only too often prevents effective relief being given to them in their troubles. The story is briefly as follows. A servant girl in a situation at Bath felt so ill that she returned to her home in Devizes. Within a few hours of her return she died from peritonitis. The jury indicated a wish to add to their verdict some words censuring the girl's mistress at Bath for not calling a medical man to her aid, but the mistress was able to show that the girl absolutely refused to see a medical man until she got home. So she took a railway journey on a cold day when very ill and died at the end of it.

This reluctance of young women—generally young women of the lower orders—to see a medical man is a little extraordinary, though it is a matter which has so often been brought to the attention of the profession that it has ceased to cause surprise. The reaction is very generally attributed to the courage of ignorance. Young women have many pains and unpleasant sensations which mean little and which pass away spontaneously. Their belief that they will be better soon is founded upon experience and so usually turns out correct that when they are seriously ill, if the symptoms, unfortunately for them, are not very urgent, they neglect to take medical advice. But ignorance does not account for all instances of such behaviour. Vanity plays its share as well as the spirit of self-sacrifice which every good woman is ready to display. Among nurses in hospital practice nothing is more common than to find a fixed determination not to go off duty even when they are obviously unfit to discharge their work. They know that in many cases their retirement to bed will mean the overwork of some of their colleagues, and they dislike intensely the idea of giving up, feeling it to be a confession of unfitness for their post, and so with considerable clinical knowledge to inform them fully of their foolishness, they remain on duty until a serious breakdown is inevitable or actually occurs. Again, in a hospital there is such a horror of the hysterical subject and malingerer that no one wishes to incur a suspicion of being either. The hysterical invalid counts for so much in the labours of our hospitals that there need be no surprise at this. In a hospital a good matron should be, and generally is, quick to detect real sickness, and firm in insisting upon the stupid if well-meant act of martyrdom ceasing at once, but in a private family the assurance of the dependent that it is nothing is apt to be accepted as correct.

And there is one other point upon which we should like to lay stress. It is one that we have referred to before—namely, the attitude of many masters and mistresses towards their servants. In this case, as we know, the girl's mistress behaved with complete kindness in offering her servant medical attention, but this is not always what occurs. A large proportion of servants are at sensitive ages and are living far away from home. They have come from the country and from provincial towns, often from Scotland, and easily become home-sick, especially if there should be a lack of sympathy and a failure to make them feel welcome. One of the commonest of ailments in domestic servants is chlorotic anæmia, and it is amazing to see how often this condition is allowed to go on without notice and without treatment where the symptoms in a child of the family would quickly command all the resources of medicine. The neglected chlorosis drifts into chronicity with consequent impaired health or reaches a crisis in a gastric hæmorrhage with possibly a fatal issue. In many cases if mistresses did their duty they would not wait for the girl to complain nor assume that if she did not complain therefore all was well with her despite her looks. They would insist upon a medical man being consulted. It is no part of a master's or mistress's liability to provide medical attention for his or her domestic servants. All the same—or rather all the more—it is well to provide it for them. Servants often prefer their own medical man, but few of them are insensible to the kindness of a mistress who will offer her personal attention together with the advice of the medical man whom she consults for her own ailments and those of her children.

SPITTING AND TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I read with great pleasure in THE LANCET of Dec. 30th, 1899, the report of the preliminary meeting of the Congress on Tuberculosis and hope soon to see established all over the world sanatoria in elevated dry places for the treatment of tuberculosis by fresh air and sunlight, and our milk and meat supplies so supervised that there will be no danger of contracting these diseases from those channels. But could not spitting on the streets, in churches, theatres, railways, and other conveyances be put a stop to? Such spitting practices, besides being abominable and disgusting, may be the cause of spreading diseases and I think the matter is a police one. Means [illegible] might be [illegible] in that way be done by all the [illegible] taking an interest [illegible]

Congress beginning at once to carry pocket spittoons and using them in public? Were such practices to become fashionable the poor consumptive would not feel himself so ostracised when others are using *spittoons as well as himself.* The spittoons of persons, non-smokers, would not require to be larger than a smelling bottle, and might be elegant as well as useful. Smokers and others suffering from disease might need rather larger ones; but they could still be elegant as well as useful. The making of these spittoons would develop a new industry and give employment to many. Hoping that you will find room for this scrawl in your next issue, and thanking you in anticipation,

I am, Sirs, yours faithfully,
Paisley, Dec. 26th, 1899. J. B. HUNTER, M D Glasg.

"THE DIET OF DIABETIC SUBJECTS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 2nd, 1899, at p. 1572, I observe a query from "Glyco" concerning the diet of diabetic subjects. Perhaps it may interest him to learn that the son of the late Dr. von Dühring (not "Douring" as he states) of Hamburg is Professor Ernst von Dühring in Constantinople who has published several interesting essays on syphilis, &c. No doubt this gentleman would be able to supply some information on his father's method of treating diabetes. In general, I believe, the plan has not been supported even in Germany very warmly.

I am, Sirs, yours faithfully,
F. A. PHILIPPI, M.D.
Othmarschen, zu Hamburg, Dec. 27th, 1899.

THE ACCOMMODATION OF THE INDOOR ASSISTANT.

To the Editors of THE LANCET.

SIRS,—*May I suggest through your columns to principals who* engage indoor assistants that they should make it a rule to provide them with a bed-sitting-room or a separate sitting-room if possible? Sometimes any small poky bedroom is thought good enough for the assistant, whose chances of reading and writing are thus out of the question.

I am, Sirs, yours faithfully,
Dec. 27th, 1899. INDOOR.

"THE MACKEY FUND."

To the Editors of THE LANCET.

SIRS,—I have received the following subscriptions on behalf of the widow of the late Mr. Stephen Mackey:—*Amount previously reported,* £10 7*s.*; Mr. R. L. Legate, Bridge House, Christchurch, £2; Dr. A. Ernest Sansom, Harley-street, £1 1*s.*

I am, Sirs, yours faithfully,
LEONARD C. DOBSON, M.D. Lond.
59, Addison-gardens, Kensington, Jan. 2nd, 1900.

SEA-WATER FOR HOME USE.

To the Editors of THE LANCET.

SIRS,—Could any of your readers kindly inform me through THE LANCET of the name and address of any firm from which I could obtain sea-water in *barrels for salt water baths at home?*

I am, Sirs, yours faithfully,
St Helens, Jan. 1st, 1900. SALINE.

THE TREATMENT OF GUINEA WORM AND ELEPHANTIASIS.

A CORRESPONDENT asks if corrosive sublimate hypodermically injected has been employed in the treatment of guinea worm and if so in what strength it should be used. He also asks whether any preventive measures have been employed in elephantiasis?

"THE ANGLO-AMERICAN INSURANCE COMPANY."

To the Editors of THE LANCET.

SIRS,—You allude in THE LANCET of Dec. 30th, 1899 (p. 1870), to the arrest of the advance agent of this company. I think it would increase confidence in the *bona fides* of those who were recently acting with him as prospective directors if they took the opportunity of making their position in the affair clear and beyond possibility of suspicion. Such a course would render the success of any new company they may be promoting more probable.

I am, Sirs, yours faithfully,
Jan. 2nd, 1900. CRITIC.

LIQ. AURI BROM. ARSENATIS IN RHEUMATISM.

REFERRING to our analytical notice of this interesting gold compound in THE LANCET of Oct. 12th, 1895, p. 921, a correspondent *sends us* some experimental evidence of its beneficial effect in rheumatism. He encloses specimens of crude uric acid in the condition in which it was precipitated from urine by hydrochloric acid. He has been subject to rheumatic pains for the past two years. The first specimen of deposits, which represents what he has usually passed during the attacks, is of a chocolate colour due to a mixture of urobilin and uro-hæmatoporphyrin, the latter being significant of certain febrile conditions, especially rheumatism. The second specimen was precipitated from the urine after an acute attack accompanied by pyrexia and muscular pains. The crystals are almost black with uro-hæmatoporphyrin. The third specimen is orange-coloured and is free from rheumatic pigment. This result followed on taking bromaurum and the rheumatic pains subsided.

GRATUITOUS MEDICAL ASSISTANCE TO THE PUBLIC.

To the Editors of THE LANCET.

SIRS,—I should like the opinion of your readers on the following case:—A and B are in practice in the same town which is made up entirely of working men and tradesmen. A has his share of work and is public vaccinator. B vaccinates all he can get hold of free of charge. A has spoken to B on the matter but it has been of no avail. (A naturally does not speak to B after his refusal to stop this free vaccination.)

B allows an unqualified man to visit some of his cases. I have seen *him enter houses but cannot* prove what he does inside. I am positive there was serious illness in the houses at the time.

I should like to know to what extent these unqualified men can be used and, further, whether it is my duty to inform the General Medical Council of such a case.

I enclose my card, and am, Sirs, yours faithfully,
Jan. 2nd, 1900. LIVE AND LET LIVE.

*** *It is wrong to offer* gratuitous medical attendance indiscriminately, as the medical profession is already severely handicapped by the amount of work that is done for the public without remuneration. The limitations laid down by the General Medical Council indicate the proper use that may be made of unqualified assistants; if our correspondent can prove that B is defying the General Medical Council he can inform that body. He must beware of allowing personal animus to influence his judgment of facts.—ED. L.

ROENTGEN RAYS AT A MISSIONARY STATION.

Mercy and Truth for December states that the medical missionaries at the Peshawar station have *frequently* to deal with serious bullet-wounds and that the Rev. Dr. Welldon, the Metropolitan of India, after a recent visit to this mission gave £25 towards the cost of a Roentgen ray apparatus, the balance required being made up by three other subscribers.

WEST AFRICAN DISEASES.

A CORRESPONDENT asks to be advised as to how to obtain information with *regard to remedies for* West African diseases.

◆

Mrs. P. is strongly advised to answer no advertisement. If she or the mother advertises the strictest investigation must be conducted into *the character, means, and antecedents* of anyone who replies. An opening for fraud, to say nothing of murder, is so obviously given by such an advertisement that it will be difficult even with the *most honest and humane intention to* get any respectable paper to insert it. The best course would be to select a first-class journal and write to the editor giving assurances that an annual income will be paid for the support of the child and *not a sum down,* and that the child will be under the guardianship of its relations in its new home.

W. N. C.—The answer to our correspondent's question depends much on whether the visiting staff are permanently attached to the hospital or whether patients are to be visited by their own medical advisers. In a typical hospital in London, not a municipal institution of course, there are 184 beds, the average number occupied is 71 and there are as officers: physicians, 2; assistant physicians, 2; surgeon, 1; and resident medical officers, 2. There are also three consulting physicians. We recommend for the institution mentioned by our correspondent two *resident* medical officers and two visiting physicians.

R. F.—(1) We think our correspondent will be well advised to consult a leader of the profession in the locality. The amount to be charged should take into account his ordinary fees and the circumstances of the patient, neither of which are known to us. (2) The money is not a subject for income-tax.

Galileo.—It would be better to advertise for a ward maid, but possibly the woman for the appointment has been already selected. We do not know any institution where such partial training is given, but perhaps the nearest local hospital would help in a good work by offering facilities.

ERRATUM.—In our notice of the "Empress Puncture-Proof Bands" for cycle tyres in THE LANCET of Dec. 23rd, 1899, page 1744, the price per band should have been 5*s.* and not 7*s.* 6*d.* as there stated.

During the week marked copies of the following newspapers have been received: *Glasgow Herald, East Anglian Daily Times, Staffordshire Advertiser, Aldershot Gazette, Blackburn Telegraph, Scotsman, Hereford Times, Wigan Examiner, Times of India, Pioneer Mail, Architect, Builder, Citizen, Liverpool Daily Post, Westmorland Gazette, Truth, Yorkshire Post, Western Mercury, Bristol Mercury, New York Sun, Leeds Mercury, Kettering Leader, Western Morning News, Scarborough Mercury, Manchester Guardian, Huddersfield Examiner, Birmingham Daily Post, Gainsborough Leader, Cambridge Chronicle, Daily Argus, Birmingham, Sanitary Record, Eastbourne Gazette, Peterborough Express, Loughborough Monitor, Dundee Advertiser, Norfolk Weekly Standard, Northern Star Ulster Echo, Midland Mail, News of the World, Bath Argus.*

City Press, Reading Mercury Mining Journal, Local Government Chronicle Hertfordshire Mercury Weekly Free Press and Aberdeen Herald, Surrey Advertiser Rangoon Gazette, Hopetown Courier, Local Government Journal, Portsmouth Times Daily Courier, Hampshire Independent, Glasgow Herald, Public Health The Courrier de la Presse, Bulawayo Chronicle, Whitby Gazette, Bucks Herald, Isle of Wight Herald, Doncaster Chronicle Chester Guardian, Nuneaton Observer Halifax. &c &c.

SOCIETIES

MONDAY (8th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr C. Mansell Moullin Excision of the Vesiculæ Seminales.—Dr W J Gow: Some Remarks on the Operative Treatment of Uterine Fibroids

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40 Leicester-square, W C).—7 P.M. Council Meeting 8 P.M. Special Meeting to consider the following proposed new Bye-law: That the Council be empowered to make Grants in aid of Scientific Research in connexion with Dentistry Ordinary Meeting Adjourned Discussion on Mr J F Colyer's paper on Some Notes on the Treatment of Superior Protrusion (opened by short paper from Mr Lloyd Williams, and Mr D Hepburn will show some photographs of cases bearing on the subject) Casual Communication:—Mr E. W Harwood: The Relief of Apical Overcrowding and its Results.

TUESDAY (9th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W).—Dr F Warner: Ophthalmoplegia Externa complicating a Case of Graves's Disease.—Mr A. G R. Foulerton and Dr H. C. Thomson: Investigation into the Nature of Changes produced in the Nerve-cells of the Cerebral Cortex by the action of Tetanus Toxin.

WEDNESDAY (10th).—HUNTERIAN SOCIETY.—8.30 P.M. Paper:—Dr D Grant: Cases illustrating various Conditions giving rise to Deafness (with demonstration of cases).

THURSDAY (11th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W).—8 P.M. Specimens will be shown by Dr A. Giles, Dr Purcell, and Dr F Edge Annual Meeting Election of Officers, &c President's Valedictory Address

FRIDAY (12th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W).—8.30 P.M. Clinical Evening The following cases will be shown.—Mr J Hutchinson, jun Complete Sub-peritoneal Resection of the Os Calcis.—Mr Lunn: (1) A case of Double Facial Diplegia in a Woman (2) Congenital Luxation of the Right Hip in a Child with Skiagraph (3) Paroxysmal Hæmoglobinuria in a girl of 10 years.—Mr C J Symonds Malignant Disease of the Thyroid after two Operations.—Mr Jackson Clarke: Case of Excision of the Neck of the Lower Jaw for Ankylosis.—Other cases will be shown. Patients will be in attendance at 8 P.M.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11 Chandos-st. Cavendish-square W).—4 P.M. Meeting

LECTURES, ADDRESSES DEMONSTRATIONS, &c

TUESDAY (9th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W C).—3.30 P.M. Dr J. Taylor: Demonstration on Cerebral Tumours

WEDNESDAY (10th).—ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W C).—4.30 P.M. Dr M. Dockrell: Malignant New Growths (Post graduate Course.)

THURSDAY (11th).—CHARING-CROSS HOSPITAL.—4 P.M. Dr Green: Cases in the Wards. (Post Graduate Course.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol II of 1899, which was completed with the issue of Dec 30th, and the Title-page to the Volume, are given in this number of THE LANCET

VOLUMES AND CASES

VOLUMES for the second half of the year 1899 will be ready shortly. Bound in cloth gilt lettered, price 18s., carriage extra

Cases for binding the half year's numbers are now ready Cloth, gilt lettered price 2s., by post 2s 3d

To be obtained on application to the Manager, accompanied by remittance

---

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices and consequently inquiries concerning missing copies &c, should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance

Communications, Letters, &c., have been received from—

An Address

ON

SOME POINTS IN THE NATURAL HISTORY OF UTERINE FIBROIDS.

Delivered before the North London Medical and Chirurgical Society on Oct. 12th, 1899.

By F. H. CHAMPNEYS, M.D. Oxon.,
F.R.C.P. Lond.,
PHYSICIAN-ACCOUCHEUR TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—In selecting for this evening the subject of uterine fibroids I have been mindful of the fact that while rarities have their own special interest the most important subjects are, generally speaking, the commonest. Again, I believe it is the general experience of teachers that each year they become more elementary, not because either their own or their hearers' knowledge gets less but because they become more and more conscious of the fact that it is fundamental principles to which resort has to be generally made for the solution of problems and that these need above all things to be insisted on. I do not therefore propose to discuss on this occasion the latest discoveries in the structure or pathology of fibroids or the details of their operative treatment, but rather to go to the foundations of the subject—to inquire to some extent into their natural history: (1) how common they are; (2) what harm they do; (3) how often they do it; and (4) what follows from these considerations.

HOW COMMON ARE UTERINE FIBROIDS?

This question can only be answered approximately. In order to answer it quite accurately we should require to know the results of post-mortem examinations of all female members of the community made with due attention to the point. Clinical examination often fails to discover a small fibroid, and, indeed, many small ones may be embedded in the walls of a uterus not in size beyond the limits of normality without making their presence evident to anyone who does not search for them in the post mortem room by multiple incisions. Clinical records in hospitals must, therefore, greatly understate their frequency on the one hand, while on the other hospitals attract to themselves pathological rather than normal specimens. The latter is also true of post-mortem hospital records, and must of course be discounted. Still, if we could take notice of the cases in which fibroids occurred without causing symptoms, or at least without constituting the complaint for which the hospital was sought, we should gain an idea of their frequency.

In attempting an answer to some of the questions concerning our subject I have based my statements upon the records of St Bartholomew's Hospital. The figures will speak for themselves.

Out-patients.—From January, 1866, to July 13th, 1899 (a period of 32½ years) the number of out-patients seen in the department for diseases of women was 40,615. Of these 40,615 cases 1043 were diagnosed as cases of uterine fibroid. Therefore the proportion of cases in which uterine fibroids were diagnosed was 2½ per cent.

In-patients (in Martha Ward, for diseases of women).—From 1881 to 1899 (July 20th), 18 years, the total number of all cases was 5785. Of these 547 were diagnosed as cases of uterine fibroid. Therefore the proportion of cases in which uterine fibroids were diagnosed was 9.4 per cent. There were no in-patient notes before 1881.

Necropsies.—1. Medical post-mortem notes, 1867 to 1899. Examination was made of the bodies of 1398 women of 30 years of age and over. Uterine fibroids were noted in 74 cases—that is, just over 5 per cent. It seems probable that many cases in which small fibroids existed have not been noted. 2. Surgical post-mortem notes, 1885 to 1899 (there were no notes before 1885). The total number of examinations of the bodies of patients of 30 years of age or over was 462. Uterine fibroids were noted in 67—that is, in 14.4 per cent. It is probable that many cases of small fibroids have not been noted. In several cases in which death occurred after operations on fibroids no post-mortem examination was allowed; therefore the necropsies do not represent the total number in which the presence of fibroids was proved. Besides this, no post-mortem examination is made without permission, and none is made on a certain number dying in the hospital. The results will be seen to vary very considerably. It might, perhaps, be suggested that it would be fair to put the error in excess due to the aggregation in a hospital of pathological cases against the error in deficiency due to the overlooking of fibroids in cases in which they were not specially searched for, but I can see no reason to suppose that these errors would balance each other. I am certain, however, that fibroids, both in clinical practice and in the post-mortem room, are often overlooked. It seems to me, therefore, from the above statistics, impossible to answer numerically the question, What percentage of women have fibroids? Still, it is quite certain that they are very common, and this is generally admitted.

It is plain that the difficulty in estimating the frequency of fibroids is somewhat complex. The numbers diagnosed either in the out-patient room, in the wards, or in the post-mortem room (all of which fall below the mark, as above explained) represent an approximation to one part of the answer to the question "How *many*?" but to answer the question "How frequent?" we need to know the numbers from which these cases have been gathered. In other words, while we know something of the *enumerator* of our fraction we still have to seek the *denominator*. The out-patients themselves are *selected* from the populace, for it is plain that people do not apply to a hospital at all unless they feel in some ways out of health. The in-patients are not only selected from the out-patients but are also selected from an uncertain and unascertainable number under the care of British medical men not only in the United Kingdom but also in British possessions throughout the world.

In-patients.—With regard to the in-patients the total number of female in-patients at St. Bartholomew's Hospital from 1881[1] to the end of 1898 (the returns for 1899 are not yet completed) was 49,396; from 1870 to the end of 1898 (no figures were available before 1870) the number was 76,669.

Statements are made as to the frequency of fibroids on the authority of Klob and Bayle. In Dr. Haultain's article, for instance, in Allbutt's System of Medicine Bayle is said to state that they occur in 20 per cent. of all women over 35 years of age. The reference given for this statement is "Dict. Paris, vol. vii, p. 73," which looks like a second-hand quotation from the following: "En général, on peut avancer que la matrice est extrêmement disposée à donner naissance à des corps fibreux; car en faisant l'ouverture du cadavre du cent femmes prises indistinctement et âgées de plus de trente-cinq ans, il en est au moins vingt chez lesquelles on trouve un ou plusieurs de ces corps accidentels."[2] This is seen to be merely an impression based on no figures. The quotation from Klob[3] is as follows: "Die runden Uterus-Fibroide entwickeln sich niemals vor der Pubertät, und sehr selten vor dem 30. Jahre. Von da an steigt ihre Häufigkeit, und ist mit den klimakterischen Jahren schon so bedeutend, dass man bei nach dem 50. Lebensjahre verstorbenen Frauen gewiss bei 40 prozent mit Fibroiden bezeichnete Uteri findet." ("Round uterine fibroids never occur before puberty and very rarely before the thirtieth year. From that period their frequency increases and at the climacteric period it is such that undoubtedly 40 per cent. of the uteri of females who die after the fiftieth year contain fibroid tumours.") This is also a mere opinion and is based upon no recorded facts.

Out-patients (general).—During the period 1885-1899 (the middle of the year) 1,918,435 out-patients were treated at St. Bartholomew's Hospital and of these at least a half, or 959,217, were females. During this period there were 113 cases of fibroid in the post mortem room—i.e., 0.01 per cent. of out-patients. There were 1198 post mortem examinations, medical and surgical, on women of or over 30 years of age. Therefore fibroids occurred at the rate of 9.4 per cent. of post-mortem cases.

---

[1] There were no records from special wards previously to 1881.

WHAT SYMPTOMS DO UTERINE FIBROIDS CAUSE?

These include (1) weight and pressure; (2) bleeding; (3) pain (including dysmenorrhœa); and (4) catarrh.

1. *Weight and pressure.*—The symptoms of weight and pressure require little explanation. Any variety of fibroid, if sufficiently heavy, may cause symptoms of weight; if sufficiently large may cause pressure. If the tumour is above the pelvis pressure symptoms will be less; if in the pelvis a tumour of the size of a large fœtal head is almost bound to cause these symptoms. Pressure symptoms include the following conditions: (1) painful, frequent, or difficult micturition, even retention of urine; especially if the tumour is in the hollow of the sacrum. It must, however, be noted that even small tumours, which cannot conceivably cause symptoms either by weight or pressure, sometimes cause retention of urine. This can only be the result of reflex action; it is in this sense neurotic; it is also generally temporary. Pressure on the urinary tract may lead to cystitis and hydronephrosis, which in rare cases causes death. Pressure symptoms are generally aggravated before the menstrual flow, when the uterus and tumour swell and are generally relieved as soon as the flow is established. It is to this cyclical change in fibroids that we owe our best proof of the sanguineous afflux and physiological swelling of the uterus before menstruation and its subsidence with the establishment of the flow symptoms in cases of urinary obstruction are often very obscure, as is well known, and there may be none directly pointing to the kidneys. The ureters are less liable to be obstructed by a fibroid than by a malignant growth; since the fibroid as a rule pushes them aside, while the malignant growth infiltrates the surrounding tissues. (2) Painful or difficult defecation and very rarely obstruction. It is certain that pressure, from whatever cause, acts much more readily in the pelvis on the urinary than on the intestinal tract. This is exemplified by cases of retroversion of the gravid uterus, in which the stock symptom is retention of urine, while intestinal obstruction, or even serious impediment, is very rare. In the same way, where defecation is interfered with in cases of fibroids, it is usually from weakening of the bowel due to interference with its circulation, innervation and general nutrition rather than from direct pressure. (3) Varicose veins, as of the legs or abdomen. This symptom again is rare. Fibroids, as a rule, do not press on the vena cava inferior or on the iliac veins above the brim, these veins being protected by their situation and the tumour being generally more or less moveable. Symptoms of obstruction to veins are commoner in malignant growths, especially when the symptoms are one-sided, since malignant growths infiltrate the surrounding cellular tissue and grow round the veins In the pelvis a fibroid may cause venous obstruction and, incidentally, hæmorrhoids. (4) Pressure on the nerves, causing neuralgia, especially in the legs.

2. *Bleeding*—This takes place from the whole inner surface of the uterus, not only from the tumour; it is often apparently due to endometritis, the endometrium being often very greatly thickened, not especially over the tumour, where it is, on the contrary, sometimes thinner than elsewhere. In some cases the thickened endometrium takes the form of mucous polypi. When due to this cause curetting of the uterus may greatly modify the bleeding. In some cases the endometrium is, on the contrary, no thicker, or even thinner, than normal. As a rule the hæmorrhage is capillary; occasionally a venous sinus is opened by ulceration and severe and fatal hæmorrhage may result.

3. *Pain (including dysmenorrhœa).*—The symptom of pain may be caused by pressure and weight, but the character of the pain, and especially its general association or its general intensification at the menstrual period, point to a different cause. This cause is almost certainly painful uterine contractions. The uterus is believed to contract spontaneously at the menstrual period; with a tumour in its cavity or embedded in its substance it is hardly wonderful that these contractions should be aggravated. The spontaneous contraction of the uterus can be observed best in cases of large fibroids in which the uterus may sometimes be observed to grow smaller before the onset of the flow. Dysmenorrhœa is merely the above pain. It deserves one word to itself from the fact that patients who are not aware of having any tumour are often driven to their medical adviser by dysmenorrhœa. I am convinced that fibroids often give trouble very early, for it has several times happened to me to see a patient of the age of 30 years dysmenorrhœa and sterility, with a continuous history of dysmenorrhœa since puberty or soon after, for which the cervix had been dilated or divided in vain and in uterus was now palpably enlarged by a small fibroid, the character of the pain not having changed since its onset.

4. *Catarrh.*—This is sometimes very great. It is commonly present in, and is probably due in many cases to, endometritis of the body of the uterus. The copious colourless secretion in these cases, rather thinner than in ordinary cervical catarrh, gives us the best opportunity for studying the secretion of the uterine mucosa as distinct from that of the cervix.

As regards the above symptoms, it must be distinctly stated that subperitoneal fibroids cause no symptoms except those of weight and pressure. When a woman with a subperitoneal fibroid suffers from hæmorrhage, this is not due to the subperitoneal fibroid, but to an interstitial or submucous fibroid, since these tumours, like other misfortunes, are often not single.

WHAT IS THE MORTALITY FROM FIBROIDS.

In order to arrive at a statement on this subject it will be well to divide the cases into those which have been operated on and those in which no operation has been performed. As has already been stated, the medical post-mortem notes of St. Bartholomew's Hospital from 1867 to 1899 show that examination was made of the bodies of 1398 women of 30 years of age or over. Uterine fibroids were noted in 74 cases, or just over 5 per cent. The cases are as follows: 1. In 1873 a patient, aged 45 years, died from "repeated copious bleeding from the uterus. Convulsions preceded death." At the post-mortem examination besides other fibroids were "two large pedunculated fibroids in the uterine cavity" 2 In 1878 a patient, aged 39 years, died from diseased kidneys due to the pressure of a uterine fibroid. In 1879 a patient, aged 44 years, died from sepsis following incision of the capsule of a submucous fibroid. In 1880 a patient, aged 47 years, died from sepsis following the removal of a fibroid polypus. The following patients, who will be included later under the results of operations, also died; a patient, aged 44 years, from a sloughing fibroid, and two others, aged respectively 43 years and 46 years, from incomplete enucleation 3. In 1896 a woman, aged 62 years, died from dilation of the ureters and the kidneys, doubtfully due to the pressure of a fibroid. In all the other cases the fibroids were in no way responsible for the death of the patients. Thus we see that the mortality of the 74 cases apart from operation amounted to three, or 4·05 per cent. But if we calculate the percentage of mortality apart from operation we shall see that it took 2,160,112—that is, half of the total number of outpatients from 1866 to 1898—to furnish three cases. Thus the percentage of mortality apart from operation was 0 000138.

The surgical post-mortem notes (which date from 188 previously to which none are available) from 1885 to 1899 giv accounts of the examination of the bodies of 462 females o 30 years of age or over The number in which fibroids were noted is 67. In the following 15 cases death was due directly or indirectly to the fibroid. Two patients, aged respectively 31 years and 32 years, died from sepsis after oöphorectomy. A patient, aged 37 years, died from sepsis. The fibroid was mistaken for an ovarian tumour and was punctured after abdominal section. Two patients, aged respectively 44 years and 48 years, died from peritonitis after hysterectomy. A patient, aged 44 years, died from shock after hysterectomy. Patients died after hysterectomy at the following ages. 44 years, 39 years, 37 years, 42 years, 34 years, and 37 years. One patient, aged 50 years, died after colotomy for intestinal obstruction caused by fibroids. In the remaining 52 cases the fibroids had nothing to do with the death of the patient It will be seen that no patient died apart from operation. Cases of operations will be subsequently referred to In many cases no post-mortem examination was made

In the Martha Ward (for diseases of women) at St. Bartholomew's Hospital, of which the notes date from 1881, 5785 women were treated between 1881 and July 20th, 1899. Of these there were 547 cases of uterine fibroid—a proportion of 9 4 per cent. Out of these 547 cases there were 29 deaths, all of which, with one exception, followed operation. In the exceptional case the patient died in 1885 a few hours after admission and it is doubtful whether the fibroid had anything to do with death (no necropsy was allowed) The history was one of vomiting for several weeks, worse for a week in hospital the symptoms were vomiting and collapse The deaths were as follows After hysterectomy, 15 deaths; after oöphorectomy, two deaths, after removal of polypus, two deaths, after enucleation of the tumour, four deaths, after removal of the sloughing fibroid, three deaths, after exploratory abdominal incision one death, and after ovariotomy, one death (the fibroid caused no symptoms)

The details of operations are as follows Polypi removed 91 with two deaths (2 2 per cent), one of which occurred in 1882 from peritonitis and the other, which took place in 1895, was a case of incomplete operation on a large fibroid polypus Hysterectomy 55 operations with 15 deaths (27 2 per cent) One death occurred in 1883, five in 1894, two in 1895 three in 1896 two in 1897, and two in 1898 Oophorectomy five operations with two deaths both occurring in 1888 (40 per cent) Sloughing fibroids removed 13 with three deaths (23 per cent) One death took place in 1891, one in 1894 and one (following labour) in 1898 Enucleation 31 operations with four deaths (12 9 per cent) The deaths occurred respectively in 1885 (from sepsis), in 1888 (from pulmonary embolism) in 1889 (from sepsis incomplete operation) and in 1893 (from collapse incomplete operation) An exploratory abdominal incision was performed in one case in 1888 Nothing was removed, there was sepsis Incisions of capsule two with no death Incision and drainage of a cystic fibroid were carried out in one case The patient recovered

The following table gives the results of abdominal hysterectomies for fibroids at all the London hospitals of which statistics are published at least as far as I have been able to ascertain

TABLE I —*Showing the Abdominal Hysterectomies for Fibroids performed at Five of the London Hospitals*

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN

(210 Operations 30 Deaths Mortality 14 per cent)

Year	Operations	Deaths	Year	Operations.	Deaths
1889	14	2	1894	25	3
1890	24	0	1895	17	3
1891	19	5	1896	17	4
1892	30	3	1897	21	3
1893	23	2	1898	20	6

ST BARTHOLOMEW'S HOSPITAL

(55 Operations, 15 Deaths Mortality 27 per cent)

1883	1	1	1896	7	3
1891	1	0	1897	10	2
1892	3	0	1898	9	2
1894	10	5	1899*	7	0
1895	7	2			

* Up to July 20th.

MIDDLESEX HOSPITAL

(42 Operations 9 Deaths Mortality 21 per cent)

1890	5	2	1894	1	0
1891	3	1	1895	3	0
1892	3	2	1896	6	1
1893	0	0	1897	21	3

CHELSEA HOSPITAL

(92 Operations, 11 Deaths Mortality 12 per cent)

1894	4	0	1897	33	5
1895	6	1	1898	40	4
1896	9	1			

ST THOMAS'S HOSPITAL

(34 Operations 9 deaths Mortality 26 per cent)

1892	3	0	1895	13	4
1893	3	0	1896	5	2
1894	5	2	1897	5	1

The above figures make a grand total of 433 cases with 74 deaths, or an average mortality of 17 0 per cent Taking the mortality for each year we get the following figures —

Year	Operations.	Deaths	Percentage
1889	14	2	14 0
1890	29	2	6 9
1891	23	6	26 0
1892	39	5	12 8
1893	26	2	7 6
1894	45	10	22 2
1895	46	10	21 7
1896	44	11	25 0
1897	90	14	15 5
1898	69	11	15 9

I have preferred to take hospital statistics as a basis for arriving at the mortality from operations on fibroids to taking the results of special operators because what we are seeking is not the question how skilful any given operator may be, but what is as a matter of fact the mortality after this operation It will be seen that the mortality is even now very much the same as it was 10 years ago It must also be remembered that extensive operating tends to lower the percentage of mortality for it includes many simple and therefore less dangerous cases than would be operated on where well marked symptoms only are regarded This is a well known fact

Summary —We have now considered the subject as far as our present inquiry goes Taking St Bartholomew's Hospital as our field of investigation we see that fibroids occur in the post mortem room at the rate of 0 01 per cent of female out-patients, or 9 4 per cent —i e, 1 in 10 000—of necropsies, and that in only three cases did fibroids cause death apart from operation The mortality from operation is 17 per cent The mortality apart from operation is 3 in over 2 000 000 (2 160 112) or 0 000138 per cent It seems undeniable that deaths from fibroids apart from operation are excessively rare

The proper place for the deaths after hysterectomy is a matter for debate and must depend upon the practice of the surgeons concerned If, for instance the surgeon's practice is to operate in cases in which life is not threatened these deaths are not properly deaths from fibroids but deaths from operation, if on the other hand, the surgeon operates principally on cases in which life is threatened the deaths after his operation may be justly reckoned in large part as deaths from fibroids It seems quite evident that the mortality will be greater in the latter case also and that percentages of mortality after operation are by no means necessarily a just test either of the skill of the operator or of the correctness of his practice In this connexion it may be well to remind ourselves of the bearings of ovariotomy on hysterectomy The similarity between the two operations has rather obscured the contrast between the two diseases The natural termination of all ovarian tumours of the usual kind is death Speaking generally, therefore they should all be removed The natural course of fibroid tumours of the womb, on the contrary, is that with rare exceptions they do not cause death Speaking generally, therefore it is not necessary to life to remove them

Whether it is desirable or not to remove them depends upon the merits of each case For instance bleeding is a symptom which may urgently call for relief by operation though deaths from hæmorrhage are extremely rare A perpetually recurring severe loss of blood may ruin a life even if it does not cause death and may expose a patient to a greatly increased risk from many intercurrent diseases It must be remembered, also that long continued severe hæmorrhage is apt to destroy the power of making blood, it destroys the mint as well as the bank Pain, again though very difficult to estimate in another, may be a correct indication In this matter objective signs of suffering such as loss of sleep and affection of the pulse during the pain are to be carefully observed and are of more value than graphic descriptions on the part of the patient Pain may ruin a life though it probably never causes death Pressure symptoms apart from pain are often an urgent indication for operation Dangerous pressure symptoms almost invariably affect the urinary tract and cause retention of urine a condition which should not

very little time was available before departure from England no sufficient supply of anti-typhoid vaccine could be prepared before starting. It was therefore necessary to manufacture vaccine *en route* during the intervals which occurred in the course of the sittings of the Plague Commission in Calcutta and Agra respectively. In these places the resources of local laboratories, presided over in the one case by Mr. Nield Cook and in the other case by Mr. Hankin, were in the most generous manner placed at my disposal for the purpose of making the vaccine. The vaccine was standardised on guinea pigs which were carried about from place to place for the purpose of keeping them continuously under observation. Inasmuch as the bottles of vaccine had to be opened up repeatedly for the purpose of drawing off the material, and inasmuch as it was not possible to carry about an incubator to verify the continued sterility of the vaccine, this last was re-sterilised at 60° C. previously to undertaking each new series of inoculations. These particulars will suffice to show that the inoculations were undertaken under conditions which were very far from ideal. In particular there is reason to suppose that the results obtained (this applies notably to the inoculations done in Meerut and Lucknow which came last in series) may have been unfavourably influenced by a weakening of the vaccine brought about by repeated re-sterilisation.

Character of the vaccine which was employed.—The vaccine material which was brought out from England consisted of lysolised (1 per cent. lysol) four-week-old cultures of a virulent typhoid bacillus. These cultures had been prepared about 12 months previously They had been sterilised by an exposure to a temperature of 60° C. The quantity of culture which was employed for each inoculation varied between 0 5 and 0 75 cubic centimetre. This last was the minimum quantity which was fatal to 100 grammes of guinea-pig. This vaccine was employed in inoculations done in Bangalore and at Agra. The additional vaccine material, which was either prepared at Calcutta and Agra or which was afterwards sent out from Netley, consisted of virulent typhoid cultures which had been grown for 24 hours on nutrient agar at a temperature of 37° C. These cultures also were sterilised for the most part at 60° C. In some cases, however, a higher sterilising temperature was employed. The quantity of this agar vaccine which was inoculated varied between 0 3 and 0 5 cubic centimetre, this last quantity corresponding approximately to the quantity of culture which grew on one square centimetre of agar surface. Measured by its effects on guinea-pigs this quantum was considerably less toxic than the quantum of broth culture which was spoken of above. Both varieties of vaccine gave in the doses in which they were employed fairly severe reactions on man Unfortunately it was not in any case possible to undertake two successive inoculations.

Method by which the statistical material which is given below was collected.—The statistical material which is presented below has been compiled from information furnished to me by officers of the Royal Army Medical Corps actually in charge of troops in the various stations. This information has been supplemented by reports received from the commanding officers of the various inoculated regiments. I desire here to express my acknowledgments of the kindly assistance which was everywhere afforded me, not only in the actual carrying out of the inoculations but also in the collection of the statistics This last task has not been free from difficulty owing, among other things, to the fact that the various regiments are, in the hot season, broken up into detachments which are dispersed in the various hill stations. The whole of the information which has as yet come to hand with regard to the results of the series of inoculations referred to above is summarised in the table given on the following page.

Taken as a whole the statistical material given herewith, though it cannot from the nature of the case be assumed to be either complete or free from errors, would appear to show conclusively that a certain measure of protection was conferred by the inoculation of the quantities of dead typhoid culture which have been specified above. In appraising the amount of that protection from the data which are given above the following facts must not be lost sight of:—1 The inoculated men in the above units were, taken as a whole, in practically every case men who were much more liable to contract typhoid fever than the uninoculated men; for in practically every case the inoculated consisted to a large, and sometimes to a preponderating, extent of young men who had only recently come out to India, while the uninoculated consisted to a very large extent of older and more seasoned—in other words, of less susceptible—individuals. It was in every case pointed out in the preliminary lecture in which the facts regarding anti-typhoid inoculation were laid before the men, that the young and susceptible new-comers were more particularly in need of the protection which, it was hoped, would be afforded by the inoculations. The commanding officers and the company officers, further, in many cases used their influence to get, so far as this was possible, all the young and unseasoned soldiers to volunteer for inoculation.

Read in the light of the above facts many of the results appear under a much more favourable aspect than that in which they appear on a mere inspection of the figures given in the table above. Thus, for instance, in the case of D Battery Royal Horse Artillery, a consideration of the facts will show that the results of inoculation are not fairly gauged by the fact that the sole case of typhoid fever which occurred in the battery was a case which occurred in an inoculated man.[5] The following were the circumstances under which the inoculations were done. The battery in question had only arrived from England a few months previously to the date of inoculation. On the previous day the battery had lost its first man from enteric fever. Owing to this and other favouring circumstances more than half of the battery, including most of the men who had come out from home, volunteered for inoculation. Those who did not volunteer for inoculation consisted in large part of seasoned men who had been transferred to this battery after its arrival in India. In view of this it will be manifest that the fact which deserves notice here is not so much the fact that one case occurred in the inoculated, while no case occurred in the uninoculated; it is rather the fact that a battery consisting in large part of men newly arrived from home has in the 11 months subsequent to the institution of the inoculations had only one case of enteric fever. The same thing holds true of the inoculations done in the 2nd Battalion Gordon Highlanders. Here, again, we have a body of inoculated men consisting in predominant part of men who had just come out from home; while we have a body of uninoculated in which there was a large element of seasoned soldiers who had been taken over from the battalion which had just returned to England. The figures given in the table for this regiment, which are already very favourable to inoculation, become much more strikingly so when they are considered in connexion with the circumstances which have just been detailed.

2 It must further be borne in mind in connexion with certain of the statistics which have been given above that the inoculations were in certain cases undertaken in the actual presence of a typhoid fever epidemic. These were the conditions in the case of the Gordon Highlanders at Umballa and more particularly in the case of the 3rd Hussars in Lucknow. In the case of the Gordon Highlanders 30 cases of enteric fever had occurred during the three months which had elapsed between the arrival of the regiment from England and the institution of the inoculations. In the case of the 3rd Hussars some 10 deaths from enteric fever had occurred in the interval of a few months which had elapsed since their arrival in India. In like manner a few cases of typhoid fever were occurring in the York and Lancaster Regiment at Agra at the time of inoculation. In conformity with the fact that inoculations were done in these cases in the presence of typhoid fever it was only to be expected that some of the inoculated would prove to have been incubating typhoid fever at the time of the inoculation This turned out to be the case in the 3rd Hussars, five cases of enteric fever (occurring among the inoculated men) being admitted to hospital within the first 19 days after inoculation. In two of these cases there was a definite history of the men having been ill previously to inoculation. One similar case occurred among the inoculated in the York and Lancaster Regiment within a few days after inoculation These cases have been distinguished by italics in the table, and they have not been reckoned in the general summary of cases contracted subsequent to inoculation.

3 Lastly, it is to be borne in mind that the results given above apply to men as distinguished from officers. In the

---

[5] The case in question was a somewhat anomalous one It was the case of a man who, while in hospital for an injury to the foot, suddenly developed a high temperature and died within 24 hours The post-mortem examination revealed ulceration of the intestine which was diagnosed as typhoid ulceration

my attention has been called from several different quarters to the possibility that the anti-typhoid inoculation may confer a certain protection against malarial fever. In the case of one particular regiment I have been furnished by the commanding officer with lists personally prepared by the company officers giving with respect to each inoculated man particulars as to whether he had suffered from "fever and ague" (*a*) before inoculation; and (*b*) after inoculation These lists, compiled six months after the date of inoculation, show that of 121 men who had previously suffered from "fever and ague" 111 declared themselves to have been quite free since, the remaining 20 declaring themselves to have been practically free Only two men who had not previously suffered from "fever and ague" declared themselves to have suffered slightly since In view of these statements the question as to whether any protection against malarial fevers is in reality afforded by an injection of a dead typhoid culture may, in spite of the *a priori* improbability of such being the case, perhaps be deserving of attention.

Netley.

PLAGUE IN RELATION TO SINGAPORE.

By MAXIMILIAN F. SIMON, M D ST. AND.,
PRINCIPAL CIVIL MEDICAL OFFICER, STRAITS SETTLEMENTS AND HEALTH OFFICER, PORT OF SINGAPORE.

THE following remarks on the experiences of Singapore during the past six years may be not without interest as illustrating to a certain extent some points in the nature of plague as regards the facility or otherwise of its transmission by sea

The geographical position of Singapore, between India and the West generally on one side and China and the Far East on the other, has given the place the position which it holds as a very large centre of trade Besides merchandise Singapore receives from China for employment locally and for transmission to Java, to Sumatra, to the States of the Malay Peninsular, and to other places immense numbers of Chinese immigrants. It also receives immigrants from India, though in less numbers, as the larger proportion of these disembark at Penang It is manifest, therefore, that Singapore is markedly exposed to any danger which may exist as regards transmission of plague by sea when that disease is prevalent in the countries from which these immigrants come

The quarantine regulations at Singapore have now been for many years assimilated as nearly as possible to those of the port of London, and they may be described shortly as consisting mainly in the principles of inspection, isolation, and disinfection. The system, however, differs from that of England in that, as it would be quite impossible to trace immigrants after landing, they are, after removal from their ships, detained under observation at the quarantine station, where there is accommodation for nearly 2000 persons, until the period of incubation since the last risk of contracting infection is passed, unless such period has already been passed on board, the ship in the meantime, after disinfection if necessary, being allowed *pratique* These regulations have been found to work very satisfactorily and with the least possible delay to trade

In 1894 plague was prevalent in Hong Kong from May to September and it was found necessary to stop immigration from Hong Kong from June 19th to Sept 21st, before and after which date it was allowed as usual, and thus it went on in May and June while plague was bad for about six weeks In that year 72 289 immigrants were inspected on account of plague On June 14th in an undoubted case of plague the patient was landed from the steamship *Paklan* The sufferer was a Chinese fireman who had fever, delirium, and inguinal buboes He was landed at the quarantine island and after a long and serious illness he recovered No attempt had been made to isolate him from the other firemen with whom he had freely communicated. The crew and immigrant passengers were kept under observation for nine days and no other case occurred In 1895 plague prevailed, but not to a great extent, in Macao, Swatow, and Hainan In that year 108,635 passengers were inspected on account of plague, but no case was detected. In 1896 there was plague in Hong-Kong from February until August, in Hainan from April until September, and on the southern coast of China from June until September. In this year 145,814 passengers were inspected, and on March 5th one case of plague was found on the steamship *Wingsang*, from Hong-Kong, the patient being a coolie passenger; he died on the next day. No attempt at isolation had been made, but no further cases occurred among the passengers while under observation. During that year five doubtful or suspicious looking patients were landed from various ships In 1897 there was plague in Hong-Kong, but not to an epidemic extent, very few cases occurring from May to the end of the year, in Amoy from June to October, and in Swatow from April to November—immigration from these two places being prohibited for a certain period of the year. In this year, also, plague was prevalent in Bombay and Western India from March onwards. During the year 115,542 passengers were inspected, and one case strongly resembling plague was found, which ended in recovery after three weeks' illness. A considerable number of "doubtful" patients were landed and treated in isolation during the year. In 1898 Hong-Kong was proclaimed infected from March to August, but immigration continued. Calcutta was declared infected from May to October, and the western coast of India throughout the year. During the year 144,686 passengers were inspected and three cases of plague were found—two Chinese immigrants on the *Keong Wai* and one, an Indian soldier from Hong-Kong, on the *Lightning*. The two Chinese had fever and delirium, and one had a submaxillary bubo and the other an inguinal bubo. Agar-agar tubes inoculated from the blood of these men in one case failed and in the other it yielded an almost pure cultivation of the plague bacillus Both men died within 24 hours. The Indian soldier, in whose case, also, the disease was verified by cultivation from a deep puncture into an inguinal bubo, died in three days from pneumonia Three "doubtful" patients were treated in isolation this year and all recovered. No attempts at isolation had been made of the three plague cases, but no other cases occurred during nine days' observation among the other immigrants In 1899 Hong-Kong was proclaimed infected from March 15th to Oct 15th and the southern coast of China from June to September, Calcutta was declared infected in February and still remains so, and the proclamation against Western India has remained in force. It was found necessary to prohibit immigration from Hong-Kong, Swatow, and Amoy from June until October. In this year up to date 139,158 immigrant passengers have been inspected and 10 cases of plague have been found, as noted in the following table:—

No.	Ship.	From	Sex of patient.	Date of admission to Quarantine Hospital	Result.
1	Kutsang	Hong Kong	M.	May 8th, 1899.	Died May 9th, 1899

10	Hyson.	"	F.	June 7th 1899	Died June 8th, 1899

REMARKS

Nos 1, 2, and 3 all had fever and delirium; No 1 had a large axillary bubo, No. 2 had an inguinal bubo; in No. 3 no bubo was discovered Agar-agar tubes from the blood of No. 2 and No 3 (the latter from a vein in the neck after death) gave growths of plague bacilli There had been three deaths on board the *Kutsang* during the voyage from [illegible]

Major Firth, and which were supplemented by some further inquiries made by me that none of these officers have suffered from enteric fever, whereas two uninoculated officers who came out in the same troopship have succumbed to that disease plague—two with fever and bubo, and one with no bubo. The three men who died on board, with the three men who died in Singapore, and another man who remained healthy, seven men in all, were all members of one family, from a village near Swatow. There was no, or very little, attempt at isolation. There were 774 immigrant passengers on board, but no further case.

No. 4 was a case of Inguinal bubo, the cultivation from the blood being characteristic. There was no attempt at isolation. There were 609 immigrants on board, but no other cases.

Nos. 5, 6, and 7.—As regards these cases see text of the paper. Cultivations from No. 5 and No. 7 gave doubtful results, but there was really no doubt as to the diagnosis. A cultivation from blood from a vein in the neck after the death of No. 6 gave characteristic growth and bacilli. There was no isolation. There were 484 immigrants on board, but no other cases during nine days' observation from May 24th. Two deaths had occurred on the voyage down from "high fever."

No. 8.—One death, of a child, said to be from acute bronchitis, had occurred on the voyage down; this patient was the mother of the child. Fever, afterwards delirium, inflamed gland at the elbow, and cellulitis of the arm were noted. A cultivation from blood gave characteristic results. The patient had been isolated for two days on board. There were 874 passengers on board, but no other cases.

No. 9.—Died on board prior to landing. There was enlarged femoral gland with bloody exudation around. A cultivation made from a scraping from the centre of the gland gave characteristic results. There had been no isolation. There were 732 immigrants, but no other case.

No. 10.—In this case there were fever, dazed appearance, femoral bubo, and congestion of the lungs. A cultivation from the blood gave characteristic results. There had been a doubtful short isolation on board. There were 812 immigrants, but no other cases.

In the eight out of the above 10 cases which ended fatally (with the exception of Case No. 1, in which the nature of the disease was so absolutely certain that no attempt at verification was considered necessary), cultivation growths showed characteristic plague bacilli. In the two cases which ended in recovery, though the growths which resulted from cultivation from the blood appeared to be characteristic, on microscopical examination the usual characters of plague bacilli could not with certainty be identified, the appearances rather resembling those of diplococci, but there is no reasonable doubt as to the correctness of the diagnosis of the disease in both cases. In this bacteriological work I have received much kind help from Dr. W. R. C. Middleton and Dr. J. A. R. Glennie, medical officers to the municipality. During this year five "doubtful" cases were treated in isolation, all ending in recovery.

In each year numerous cases of fever, detected on inspection of immigrants, were detained for a few days under observation. Over 200 of such cases were detained in 1898 and there have been over 300 of such cases up to date this year. None of these cases are included among those which I have called *"doubtful" cases of plague; these latter I* shall refer to later.

The voyage from Hong-Kong to Singapore takes from five to seven days, that from Swatow and Amoy to Singapore a day or two longer

In none of the cases of plague that were detected, except in two or three in 1899, as noted in the table above, in which the patients had been isolated on board for two or three days, had any attempt at isolation of patients been made until the cases were detected in Singapore. In every case, after isolation of the sick at Singapore, the remaining immigrants were kept under observation with frequent inspection for nine days and on no occasion, except that of the *On Sang* to be referred to hereafter, did any further cases of disease occur. During the whole six years no attempt had been made to disinfect cargo or passengers' baggage, except that the clothing and baggage of the sick were of course dealt with.

As regards the *On Sang* the first patient whose case was detected on arrival was a woman who had fever, a certain amount of cerebral disturbance, and a large femoral bubo, consisting of more than one inflamed gland, very tender, and with surrounding exudation. She was, of course, isolated on arrival, and a man, a relation of hers, chose to be isolated with her to help in looking after her. In four days after this a man among the rest of the passengers was found to be very ill with fever, and examination revealed a comparatively small, recent, and very tender inguinal swelling and a large popliteal glandular swelling with the skin over it of a purplish colour and apparently commencing to slough. He died on the next day and plague was verified after death. The unusual situation of the bubo, in the popliteal space, may account for this patient's having been overlooked before, or he may have evaded inspection in some way until he became too ill; he turned out to be the husband of the sick woman. On the following day the attendant on the woman, who was also a relative, was found to have fever and a characteristic inguinal bubo, and there is no doubt that this was a mild of plague though bacteriological evidence was not conclusive. These three people came from the same village and there is no doubt, I think, that they brought the infection with them in some way. The husband mixed with the other immigrants for two or three days after his arrival here and no doubt he had been ill for some days before, but he did not spread infection.

It will be observed that in each year except 1894 and 1895 a certain number—in some years a good many—of what I have called "doubtful" cases have been detected among immigrants and treated in isolation. All these cases presented symptoms of fever, sometimes rather high fever, and had buboes without any obvious cause for them. The buboes were, for the most part, femoral or inguinal. They were all tender, *and in all cases they presented the* appearance of an enlarged gland or glands, fixed, with exudation around them, and the skin over them in a few cases slightly discoloured. All these cases recovered without the buboes going on to suppuration, and from none of them in which trial was made could cultivations of the plague bacillus be obtained, some inoculations of tubes proving sterile, others resulting in the growth of a coccus.

I do not for a moment pretend that individual immigrants may not on occasions have evaded inspection; indeed, it would be wonderful were it not so, or even that some doubtful cases may have escaped notice, but I am confident that no case of plague has been overlooked. So far as I know there has been during these six years no case of plague in Singapore, though we have had false alarms on several occasions. Dr. Middleton, the municipal health officer, agrees with me as to this point. I am confident that had cases occurred, even in very moderate numbers, we should have found them out as the occurrence of cases in Penang was discovered.

The following points are, I think, worthy of notice in connexion with the above particulars. 1. The very small number of plague cases detected among immigrants, at least up to 1899, notwithstanding the prevalence of the disease in China. This is, no doubt, in some measure to be accounted for by the fact that at most, if not all, of the Chinese ports coolies were medically inspected before departure. 2. The *fact that (except as regards the cases from the On Sang,* which are explained above) although, as I have stated, no attempts, *except in one or two instances in 1899*, at isolation of the sick on the voyage were made, still in no single *instance during the six years has* the disease spread among immigrants who have had cases of plague mixed up with them for several days. 3. The question as to whether the disease may not be capable of modification when a sufferer is removed *from the infected environment.* It has long been thought, though some instances of late years seem against it, that plague cannot live within a certain distance of the equator—that it is not a disease of the central tropics. A *late limited outbreak of the disease in Penang,* four degrees north of Singapore, which *is itself* less than one and a half degrees north of the line, certainly shows that cases can occur in that latitude; but there *is* no doubt that the germ did not propagate well in that outbreak or it would have been much more severe than it was, and it still remains to be seen if there will be any recrudescence. Again, I believe that the disease has travelled further south in India than has ever been known before, but though there were some cases in Madras it did not gain any footing there. As regards Ceylon, the southern end of which is in a latitude very little north of that of Penang, I believe that in ships coming there from Bombay and the upper parts of the west coast of India the conditions have been very similar to those found here—viz., very few cases have been detected, or have occurred, on board—and that in *none* of these has the disease spread. With regard to the cultures it was found that about eight days was the limit of their life. Taking into consideration the fact that with the exception of the 1894 case, which was a bad one, all the cases which had the disease badly and in which the bacilli could be with certainty identified speedily ended in death; that the few cases which were not so severe, but as to the nature of which there was no reasonable doubt, could not be bacteriologically identified with certainty and ended in recovery; and that the numerous doubtful cases which presented symptoms, not perhaps very severe, closely resembling those of plague, also could not be verified and all ended in recovery, it seems to me that the disease is susceptible of modification or that it can abort.

From one case we can never tell with certainty what may happen in the future, but the history of the experiences of Singapore up to the present date seems to indicate (1) that plague is not readily transmissible by sea far south of localities in which it is epidemic or endemic, and that should it in later years spread more towards the equator it will do so probably by slow extension overland, the germ becoming gradually acclimatised; (2) that when removed from endemic environment the disease is not at all readily communicable from person to person; (3) that the danger of conveyance of infection by cargo and baggage for any distance by sea, at all events below what has been thought its boundary of latitude, is practically nil; and (4)—but this indication I submit with a certain amount of diffidence—that, unless a patient has received a very strong dose of infection or unless the morbid process in the body has reached a certain point prior to embarkation, when a patient leaves the infected environment and travels by sea towards the central tropical zone the disease has a tendency to abort. The bacilli either disappear in some way or become modified and inert, leaving the patient to gradually lose the fever which has been deprived of its specific exciting cause and to recover from the glandular affection, which having also lost the specific cause of its access and increase, tends to resolve in the same way as after ordinary inflammation.

Singapore.

CASE OF PERFORATED GASTRIC ULCER ON THE POSTERIOR SURFACE OF THE STOMACH; OPERATION; RECOVERY.

BY SAMUEL DAVEY, M.R.C.S. ENG.,
L.R.C.P. LOND., D.P.H.;

WITH REMARKS

BY FREDERIC EVE, F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

ON Nov. 6th, 1899, I was called about 1 P.M. to see a married woman, aged 38 years, whom I had attended on two previous occasions—viz., in April and June of 1899—with symptoms which undoubtedly pointed to the presence of a gastric ulcer. On my arrival at about 1.30 P.M. I found the patient in an extremely collapsed condition and elicited from her (she was only able to utter words in monosyllables) the following history. Since she had seen me in June she had been fairly well, with the exception of occasional attacks of "indigestion," until that morning, when about 11 o'clock she was seized with an acute and sudden pain in her "stomach," which she localised over the whole of the epigastric region, but stated that the pain was much worse on the left side of the abdomen, the area indicated being of about the size of one's hand and immediately over the cardiac end of the stomach. The patient was lying on the couch with the legs flexed on the abdomen; the abdominal muscles were extremely rigid and the slightest attempt at manipulation of the abdomen caused severe pain. The extremities and the tip of the nose were quite cold and the pulse was quick and small. She had vomited twice, but blood had not been noticed. Unfortunately, the vomit had been thrown away. At three o'clock I saw her again and found her much in the same condition; there had been no more vomiting, but the state of collapse was just as great. I now had her carried into her bedroom, the frequent application of external heat which I had ordered on my first visit being continued, and I also injected hypodermically a quarter of a grain of acetate of morphia. Mr. F. Eve, to whom I had previously wired, arrived at about 6.45 P.M. and saw the patient with me. Meanwhile a marvellous change had occurred in her condition; the pain had quite disappeared, the legs were extended, and the rigidity of the abdominal muscles had to a very great extent subsided. With the exception of some coldness of the nasal tip all the symptoms of collapse had passed away, in fact, so far had the patient recovered that she expressed herself as being perfectly comfortable. Since my visit at three o'clock the temperature had risen to 102° F. and manipulation of the abdomen could be carried out without giving rise to pain. The possibilities of the case were carefully explained to the friends and the patient and an exploratory operation was strongly advised; to this procedure the friends and the patient readily agreed.

The patient being under chloroform and strict antiseptic precautions being observed, Mr. Eve opened the abdomen in the middle line, the incision being about five inches in length and commencing about two inches below the ensiform process. When the peritoneal cavity was freely opened a very small amount of turbid peritoneal fluid welled into the wound. The anterior surface of the stomach now presented itself and although a careful search was made no perforation could be detected. On tearing through the great omentum a few recent flakes of lymph were observed adhering to the posterior surface of the stomach, near the lesser curvature. Although careful inspection was again made no perforation could be found. Mr. Eve now divided the left rectus muscle horizontally, parallel with the costal margin, in order that a better view of the stomach might be obtained. The stomach was gently drawn out of the abdomen and turned upwards when a perforation on the posterior surface close to the lesser curvature and attachment of the lesser omentum was seen. The gastric juice welled slowly from an opening just large enough to admit an ordinary probe, and around the orifice was a disc-shaped induration of the stomach. The perforation and adjacent area were stitched with about eight Lembert's sutures so as to cause an infolding of the wall of the stomach at this part. All visible flakes of lymph were sponged away and the abdominal cavity was thoroughly washed out with boiled water. A Keith's tube was inserted in the lesser cavity of the peritoneum and the wound was closed in the usual way.

There is nothing special to report in the after-history of the case. The temperature fell to normal by midnight of the day of the operation. The Keith's tube was removed on the fourth day and the stitches on the tenth; the abdominal wound healed throughout by first intention. On Dec. 4th, 1899, a month after the operation, the patient was up and able to walk slowly from one room to another.

Remarks by MR. EVE.—The most noteworthy feature of this case was the remarkable manner in which the symptoms of perforation had passed off when I saw the patient, although she had only had a quarter of a grain of morphia four hours previously. She did not appear ill, had no pain, and no tenderness could be elicited even on applying firm pressure over the epigastrium. The points which in our opinion justified an operation were the previous definite history of ulcer of the stomach, the very typical symptoms of perforation observed by Mr. Davey, the presence of a temperature of 102°, together with slight rigidity of the abdominal muscles, and the absence of any lesion of the thorax or elsewhere to explain the temperature and previous symptoms. My hands were very much strengthened by Mr. Davey's very firm conviction that perforation had occurred.

When asked if I would postpone operating until the following morning and see the patient again then, I declined to do so on the ground that if the perforation existed the chances of recovery would be greatly discounted by the delay. The perforation was only found after minute examination. This was due to the small size and the very slight amount of fluid oozing from it. Its site was determined by a well-marked induration of the stomach wall around it and the presence of a few patches of lymph in its neighbourhood. Although the opening was situated on the posterior wall close to the lesser curvature and about from one and a half to two inches from the cardiac orifice there was no difficulty in exposing it or inserting the sutures. No free gas existed in the abdominal cavity. When present I think it is mainly the result of decomposition. Cases of peritonitis due to gastric ulcer are recorded in which the abdomen was full of gas although no perforation existed.

HEALTH OF PLYMOUTH.—At the meeting of the Plymouth Borough Council held on Jan. 8th the medical officer of health (Mr. F. M. Williams) stated that the death-rate for 1899 was at the rate of 21 per 1000, showing a slight increase over that for 1898, an increase which was principally owing to a heavy mortality from infantile diarrhœa during July and August. Mr. Williams also alluded to the present high death rate in Plymouth, which, he said, was largely caused by diseases of the respiratory organs, and he expressed a hope that the council would endeavour to abate the crowding that existed and provide more air spaces and better dwellings.

A NOTE ON SOME FURTHER EXPERIENCE OF OPERATIONS UNDER LOCAL ANALGESIA PRODUCED BY EUCAINE β.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE.

AT the beginning of last year in a "Clinical Lecture and Demonstration" delivered at University College Hospital[1] I drew attention to some of the leading features of the method of local analgesia which has of late been practised in many parts of the world. Since then I have given the procedure a fairly extended trial and on the basis of all the cases treated in this way by myself, during the year 1899 I venture to offer some further remarks upon the subject.

In the first place, it may be stated that all the patients enumerated below, except one who was delirious, elected after due explanation to have the operation performed under local analgesia. Any who objected decidedly were not urged to have it. A good many expressed a strong desire for it either because they had a dread of general anæsthesia from previous experience or for other reasons. I believe that I am correct in stating that not one of those who were operated on under local analgesia alone regretted it. And it may further be stated that several who had had a previous experience of chloroform or ether and for subsequent operations selected eucaine β, expressed themselves as more than pleased with their choice. Some of these latter had, for instance, had one radical cure for hernia done under general anæsthesia and the other on the opposite side under local analgesia, other conditions being equal.

The first point which comes out of a study of our series is the fact that no ill-effect has followed the use of the normal saline solution with 1 in 1000 of eucaine β added to it which has been employed for local analgesia. Not only have no toxic troubles arisen, even when five or six ounces of the solution were used, but the primary union of the wounds has not been in the least interfered with. The only thing which I have noticed as possibly a specific effect of the drug was free sweating in several cases and pallor in a few. But this might have been due to other causes, as also that a very few of the patients vomited during the operation, and I think it was. In long operations I have sometimes used as much as six ounces of the solution and certainly without any ill-effect. This is only what one would expect from the harmlessness of even larger quantities given to animals. But if it is quite clear that there is little, if any, immediate or subsequent ill-effect from local analgesia produced in this way it is equally plain that there are certain limitations to its use. Children, for instance, appear to be unsuitable subjects for this procedure. The mere sight of the surgical preparations for operation frightens them and their unstable emotional condition is upset by the slightest pain. Very timid adults for the same reason are also better dealt with by general anæsthesia. If the part to be operated on is acutely inflamed I have found it very difficult, if not impossible, to render it quite insensible to pain, although in one case of typhlitis and general peritonitis I find it noted that from beginning to end of the operation there was no trace of pain, though the patient showed no evidence of blunted feeling otherwise. Again, it must be remembered that this procedure only causes *local analgesia* and in many operations it is next to impossible to render insensible all the structures which may be affected by the manipulations of our operation. For this reason when the intestine is being resected it is necessary to avoid all drag upon the mesentery which is beyond the reach of the injection, otherwise the patients state that they have a feeling as if the abdomen were being "pressed upon" or they may say that there is griping. In one case of posterior gastro-enterostomy, for instance, which was on the whole borne by a delicate woman extremely well the necessary lifting out the stomach for diagnosis produced this feeling and even vomiting. When the organ was allowed to slip back the rest of the
without any pain at all
recovery. Again, in operating for the radical cure of inguinal hernia, of which I have had many cases, I have noticed that if the cord is much dragged upon the strain is productive of great discomfort, but that if it is fully injected as high up as possible and separated from the sac without
no pain is complained of. This also applies to the omentum and sac and I have often asked the patients to note particularly when I was ligaturing these structures and cutting them off, and they have told me that they felt nothing. The same was seen well in three cases in which I have recently operated for the removal of considerable thyroid adenomata of the size of an orange. The incision, a large one, and the subsequent dissection were painless, but on drawing out the tumour to get at the last deep attachments the patients stated that there was a "pressing" sensation in the neck. It was not severe, but was worth noting. In one other similar case of thyroid disease where there was a good deal of bleeding, and where it was necessary to hurry, I gave chloroform for the last part of the operation.

There is another drawback to this method which deserves notice if only to show that it is a trifling one. When the fluid is first injected the result is to produce a distension for a time of the areolar spaces, so that an appearance of artificial œdema is seen. This undoubtedly makes the first dissection less clear for the moment. This condition does not last long as the fluid trickles out of the wound and I have come to disregard it altogether. But to the beginner it is disconcerting to some extent. Another point, too, deserves notice in reference to the actual dissection. If this is carried out by *rapid* cuts or snips with scissors the moment of division of small vessels is felt as a twinge, whereas if the cuts are made more deliberately with knife and scissors nothing is felt as a rule. All these facts tend to diminish the rapidity of operation somewhat, which is a drawback from the surgeon's point of view. But this is compensated for to the patient by the absence of sickness after the operation and the fact that he can enjoy food in many cases at once, indeed many have enjoyed their cup of tea during the operation. The cases which appear to be most suitable for this procedure are those in which there is considerable danger of lung complications following the use of chloroform or ether. In intestinal obstruction, for instance, in weak or elderly persons this is peculiarly the case. They have often suffered for days from stercoraceous vomiting and have been recumbent and will have to remain so. In such cases no one can deny the danger of keeping them for a long time under the influence of general anæsthesia, especially as they will often be sick after recovering from the anæsthesia and consequently cannot be fed or stimulated by the stomach. In such cases the local analgesia answers admirably, and I have no hesitation in urging these patients to it if they are not strongly opposed. Again, a colotomy or resection of gut under these conditions is a typical case in point and such patients will thank the surgeon afterwards for having spared them the use of chloroform. Quite recently I have done a colotomy on a lady in the country who dreaded *general* anæsthesia. Under eucaine β she felt, she said, practically nothing of my manipulations from the first cut to the last stitch and was very grateful for the local analgesia, as she had experienced the unpleasant effects of the general anæsthetics on several occasions in former years. Again, in cases of empyema, where it is often questionable whether chloroform or ether will be safe, I have found local analgesia very satisfactory. But here it must be remembered that in the deeper structures hyperæsthesia will be present owing to the inflamed state of the pleura and costal periosteum. It is necessary then to be very careful in injecting very fully the whole area of the deeper structures to be dealt with. And even so, perhaps a little pain will be felt as they are divided. But this is a small price to pay for the avoidance of the ill-effects of chloroform or ether in such cases. In two cases now in my wards operated on for empyema on phthisical patients this is well illustrated and the patients if asked will give a very good account of the procedure. In one other I had to complete the operation under chloroform as a piece of rib had to be excised.

But there is no doubt that the method requires considerable practice on the part of the surgeon before he can obtain the best results. This I can vouch for after carefully working at it for more than a year and a half, during which a considerable variety of cases have been treated by it. It is necessary to have, in the first place, a good syringe easily sterilised and good and particularly fine needles. The proper solution must be warm when used and must be fully distributed over the area to be dealt with. Five minutes or so after its introduction the tissues are ready for operation and in about 20 minutes they will require fresh injection. Deliberate dissection and handling must be cultivated and all dragging and tearing as far as possible be avoided. The operating table must be made as comfortable as possible for the patients, who are fatigued and sore if placed upon a hard surface and required to remain motionless for long. Some kind of screen between them and the operator is desirable. I usually put a small cradle over the head and over this a towel. If there is no special reason against it these patients will be cheered and strengthened by a cup of tea or some stimulant before and during the operation. In some cases of excitable patients a small preliminary hypodermic dose of morphia has seemed to be of benefit.

---

[1] THE LANCET, Feb. 4th, 1899, p. 282.

All these points, and doubtless many others, require to be learned step by step and each case teaches something which will perhaps be useful in the next. At first the surgeon suffers from the feeling that he may be causing pain to the patient, and this is a certain check to his manipulations. There is something "uncanny" in making a dissection on an individual who is perfectly conscious and perhaps talking to you at the time, and it is hard to realise that he is not suffering and consequently the surgeon may hesitate. But when a few cases have been operated on in this way and we are sure of our position this hesitation wears off and we proceed more rapidly, to the patient's great benefit, of course. Some of the cases, I must say for myself, have filled me with amazement The patients have appeared perfectly indifferent and very often in the best of spirits all the time. Even those who feel a little pinch or drag here or there make light of it as a rule. I heard one patient humming a tune to himself during a radical cure of hernia which I was doing.

The cases in which during the year 1899 this mode of operating has been selected for some of my patients for one reason or another arrange themselves in the following groups:—

Radical cure of hernia	15
Herniotomy for strangulation	1
Resection of intestine for gangrene	1
Gastro-enterostomy	1
Abdominal section for epityphlitis	2
For perforated gastric ulcer	1
For carcinoma of the gall bladder (exploration) .	1
Removal of goitre	4
Gouging carious bone ...	1
Empyema	4
Varicocele	1
For varices on legs	5
Colotomy	4
Removal of scar on the nose ...	1
Rectal cases	2
Sublingual exostoses ..	1
Salivary fistula	1
Abscesses opened	2
Removing of wire	2
Wiring patella	2
Stitching a semilunar cartilage in the knee	1
Total	53

Of these there were nine in which I thought it best, either on account of actual pain or extreme nervousness, to give general anæsthesia in the middle of the operation and to finish it under the latter. There were one radical cure of hernia, one perforated gastric ulcer, one goitre, one empyema, one colotomy, two rectal cases, one salivary fistula, and one wiring of the patella. Of these I will only say that I do not think rectal cases suitable for this procedure as a rule, inasmuch as the dragging on the bowel will usually influence parts not to be reached by the solution. Nor do I think that in a case of perforated gastric ulcer the procedure is suitable for the same reason, and besides, the peritoneum is inflamed and the operation is sure to be a long one. The salivary fistula was in connexion with an abscess and therefore unsuitable as the parts to be cut could not be infiltrated. In all the other cases I think I could now with increased experience perform the operation without pain. Selection will always be necessary, but I think that even from this limited number of trials I have learned much in this direction and that local analgesia will always be a useful procedure in certain cases, though it will not for a long time take the place of general anæsthesia. Of course the 53 cases tabulated above form but a small group in proportion to the number of operations done in the course of the year in which I have used general anæsthesia, but as far as they go they are fairly representative.

Harley street, W.

TETANUS FOLLOWING NEPHROPEXY.

BY THE LATE HENRY THOMPSON, L.R.C.P. LOND., M.R.C.S. ENG.,
SURGEON TO THE HULL ROYAL INFIRMARY.

A MARRIED woman, aged 47 years, who for years had suffered from a loose right kidney, came under my care for the purpose of having it fixed to the side. Examination showed an extremely loose right kidney which could with ease be pushed to the left side of the umbilicus. The patient was a spare, intensely neurotic woman and it turned out afterwards that for years she had been suffering from aggravated domestic troubles and had been reduced owing to the sins of others from a condition of great affluence to one of comparatively narrow means. This trouble had preyed upon her mind and together with the kidney trouble had converted her into a chronic invalid. Otherwise her physical condition was fair and a successful result was anticipated.

The operation took place on Nov. 23rd, 1898. Nothing could have been easier or apparently more satisfactory. Special care was taken both with the preparation of the patient and of the instruments, and careful thought and inquiry have failed to discover any flaw in the course of the operation. Not a single vessel required a ligature and the kidney was fixed to the periosteum of the last rib and to the muscles attached to the rib by three silk stitches which had been soaking in carbolic acid solution (1 in 20) for months. For safety's sake, in case of a vessel bleeding after the wound was stitched up, a small drainage-tube was passed down to the *kidney* and was removed on the second day. The patient apparently went on quite satisfactorily until the ninth day. The wound healed by first intention except just the track of the drainage-tube. The temperature had never risen above 99 6° F. and I considered her to be convalescent. On Dec. 1st she was told some very bad home news which upset her very much; she passed a very restless night and the next day complained for the first time of some pain and twitching in the seat of the wound in the right flank. This pain was intermittent but the hand placed upon the side could distinctly feel a spasmodic contraction which appeared to be quite involuntary. On the 4th the patient complained of some stiffness about the jaw, but the tetanic symptoms never became really severe until the day of her death which took place on the 7th, 14 days after the operation.

I can only call the above case a surgical tragedy. Nowadays under antiseptic or aseptic surgery tetanus has become one of the rarest of sequelæ. During the last 20 years the above is the only case of tetanus that I have had in private practice, and I am sure that in our hospital we do not see a case a year and those that we do see are almost invariably admitted into the hospital with the tetanus already developed. I wish to submit for consideration the following points. 1. Is there such a disease as idiopathic tetanus? or can tetanus be produced only by the bacilli introduced from without or by their toxins? 2. Granted that the bacilli may have been introduced by means of food, green vegetables, &c., can they lie dormant until some sudden accident, operation, or nervous shock sets them free or gives them a suitable soil to develop their evil ways? In my early days tetanus was always described as being of two varieties, traumatic and idiopathic, but since the discovery of its bacillus by Nicolaier in 1885 and the further development of its natural history by Tizzoni, Cattani, Faber, and others, it is now universally held that upon the impregnation of a wound by the club-shaped bacillus tetanus can alone depend. Some cases have been reported where tetanus has followed an apparently simple bruising only, but it is thought that in all such cases an undiscovered wound or abrasion has been the site of the inoculation. Tetanus has been known to follow a simple fracture and a case of that sort has been recorded by Sir George Humphry. In the above and similar cases may it not be possible that the tetanic symptoms may be due to reflex irritation of the motor centres in the spinal cord and brain by the local disturbance, rather than to any influence of the bacilli or their toxins acting through the blood? It is important to remember with reference to the possibility of the occurrence of idiopathic tetanus that the reported cases of this nature have as a rule been milder and have more frequently recovered than have the traumatic cases; still, if the now prevailing view be correct there must, in all supposed idiopathic cases have been some lesion to admit of the entrance of the bacilli, unless we allow that they may be aerially conveyed. The place of entrance may be an ulcer in the mouth, pharynx, or alimentary canal, or in some other undetected part. In horses it is said to be caused by wounds in the gums from eating straw, and cases supposed to be idiopathic have originated in this way. The tetanus bacillus has been found in garden earth, in road-scrapings, in the dust between the boards of the floors of rooms, and in the pus of certain suppurating wounds, and its special habitat seems to be soil impregnated with horse-dung. But in the case I have narrated how could any bacillus from earth or elsewhere have come in contact with the wound? A day or two before the operation the patient ate celery for luncheon. Could some bacilli have been present in the imperfectly cleansed celery and have come in contact with an abrasion in the mouth? Were the antiseptic measures in fault? Special attention was paid to them. The instruments were all thoroughly boiled and due attention was paid to the cleansing of the skin.

The last point that I wish to touch upon is the influence of mental shock upon the production of tetanus. The patient was *apparently* in quite a satisfactory state until she sustained the great mental shock in the afternoon of Dec. 1st. This upset her very much and the symptoms of tetanus developed within a few hours. Here, did the shock produce the tetanus or did it have such a depressing influence upon the patient that the previous phagocytic action was held in abeyance and the bacilli having free play rapidly developed their virulent toxins? Or was it a mere accident that the mental shock preceded the development of the tetanus with which it had nothing to do, when the reason why the tetanic symptoms developed the day after the shock would be because the period of incubation was at an end? I will not enter into any detail as regards treatment except to say that when this case was under treatment the action of tetanus antitoxin was so uncertain that, looking upon the case as a very mild one until the day of death, we did not use it. Latterly, however, I have been so much impressed by cases recently published, that I should certainly press the intra-cerebral injection of antitoxin if I should have the bad luck to have a second case of tetanus.

Hull.

SOME FACTS GATHERED FROM EXPERIENCE RESPECTING MISCIBLE BLACK CARBOLIC DISINFECTING FLUID AND CARBOLIC DISINFECTING POWDER.

THE MEANING, COMPOSITION, MODE OF TAKING SAMPLES AND METHODS OF ANALYSES.

BY FREDERICK W. ALEXANDER, L.R.C.P. EDIN., M.R.C.S., D.P.H. ENG.,
MEDICAL OFFICER OF HEALTH OF POPLAR AND BROMLEY.

WITHOUT entering into the germicidal or antiseptic or deodorant properties of "black miscible carbolic disinfecting fluid" which is used largely in solution by more than one sanitary authority for road-watering and gully-flushing, &c., I think it would be useful to the members of the medical profession who also use this disinfecting fluid in many of its various forms to make known some points which have been manifested to me when I have been obtaining analyses upon the same bulk from different analysts, inasmuch as by their varying results it must obviously appear that there is no uniform method of analysis adopted. That the result of analyses should vary even when made by the same analyst is a very serious matter not only for local authorities but also for the individuals supplying the article, as both may be put to enormous expense and great worry should the matter be contested in a court of law.

I would first give from experience a word or two as to the meaning of the term "black miscible carbolic disinfecting fluid." Unless the percentage is mentioned (which should be qualified by the words, "of tar acids and guaranteed commercially or practically free from salting.") one may be supplied with any preparation of alkalised gas tar creosote which, unless the component parts and percentage were stated, would not come under the Merchandise Marks Act, 1887. H. Mansfield Robinson, LL.D. Lond., and Cecil H. Cribb, B.Sc. Lond., F.I.C.,[1] state: "The provisions of the Sale of Food and Drugs Acts should be extended to such articles as disinfectants, antiseptics, cosmetics, and articles added to food for culinary purposes or in its preparation. By the Adulteration Acts of Massachusetts disinfectants, antiseptics, and cosmetics are included in the Act, and the necessity for such articles being covered has been shown in several districts by the sale of quantities of carbolic powder which contained no carbolic or cresylic acid. In one case the sale of such worthless powder caused an outbreak of scarlet fever through the failure of the supposed disinfectant."

A miscible black carbolic disinfecting fluid may consist simply of liquid tar oils in which in order to be made miscible or capable of forming an emulsion there would have to be employed resin, an alkali, and a soap. Such a mixture may then be offered to a local authority while containing little or no percentage of tar acids and yet be styled "miscible black carbolic disinfecting fluid," and may turn white upon the addition of water like a fluid which contains a large percentage of tar acids, and in some cases present even a more milky appearance. Fluids of this description could be manufactured, according to the market value of creosote, at from *5d.* to *6d.* per gallon, whereas a mixture containing say 35 per cent. of tar acids would entail more careful manufacturing and the price would be necessarily enhanced by the value of the percentage of tar acids. Both of these liquids (more especially if pyridine bases be present) would be very nearly alike to the sight and smell and could only be detected by crucial analysis. "Carbolic" is a name generally applied in commerce to all phenols or acids obtained from coal-tar. When a percentage of tar acids is mentioned it means in the trade total combined percentages consisting mainly of acids such as phenol (true carbolic acid), cresol (cresylic acid), and xylenol. A solution would not contain true carbolic acid alone unless one specified it and at the same time defined the acid as crystallising at definite temperatures by "Lowe's test." True commercial carbolic acid is sold by Lowe's test and generally is of the following three grades: 50° F., 60° F., and 75° F. In passing it may be stated that cresylic acid is said to have an antiseptic power considerably above that of carbolic.

In ordering carbolic disinfecting fluids it is necessary to add the words, "guaranteed commercially or practically free from salting." "Salting" appears to be the *bête noire* of the manufacturers of "black miscible carbolic disinfecting fluids." By "salting" is meant the deposit of crude naphthaline which will occur in cool weather with a black miscible carbolic disinfecting fluid which has been manufactured during a warm period of the year when it is difficult to properly extract the excess of naphthaline, a process which requires great care. When "salting" takes place the liquid becomes thick and will not flow out of the vessel.

Naphthaline is extracted from tar oils by allowing them to cool, freezing when necessary, and subsequently filtering in special machinery. This, of course, removes all except what is naturally soluble in the oil at the lowest temperature to which the oil is subjected. When purified, naphthaline can be used by a specially contrived apparatus in conjunction with ordinary coal gas to enhance the candle power of the light. Naphthaline is also manufactured into tablets and sold in chandlers' shops, &c., to the public under the name of "naphthaline" tablets or "carbon" tablets.

When specifying for the supply of "disinfecting carbolic powder," in order to obtain the full benefit of the disinfectant, not only should the percentages of tar acids be quoted, but the following words should be added, "guaranteed an inert base," by which is meant that the phenols should be mixed with a substance which merely absorbs them and does not enter into chemical combination. As to the method of taking a sample of black miscible carbolic disinfecting fluid for analysis, drawing from a tap at the bottom of the cask is not satisfactory. The following method of sampling is the "standard" one and is used for all fluids or liquids by "experts" and of course should be used by the trade generally. The barrel or cask should be thoroughly shaken, it should then be laid on its side, the bung be taken out, and the sample be taken by means of an ordinary hollow glass sampling rod, which should be passed through the bunghole to the opposite side of the barrel, thus ensuring a fair average of the whole contents of cask or barrel.

---

[1] The Law and Chemistry of Food and Drugs, p. 15.

The miscible black carbolic disinfecting fluid, of which samples were taken, was ordered from the manufacturers to contain 35 per cent. of tar acids. Seven analyses were made as follows—one by the analyst of the manufacturers and six by four other analysts. Two analysts analysed two samples each. The following is *in extenso* the result of the manufacturers' analyst: water, 15·5 per cent.; total oils to 270° C., 55 per cent.; phenols, 35 per cent.; pyridine bases, 2 per cent.; specific gravity at 60° F., 1·069; of good appearance and wholly and readily emulsifiable in water. Two of the results obtained by other analysts agreed with those of the analyst of the manufacturers. Without giving in detail the certificates of analysis of the remaining four samples, the phenoloids or tar acids as certified were respectively—28·7 per cent., 24·6 per cent., 23·0 per cent., and 13·7 per cent. In some of the certificates other items were given, but tar acids were specially asked for when sending the samples and I give them as quoted in the results.

The varying of the percentages of tar acids and the wording of the certificates suggest that analysts adopt different methods of analysis. By the kindness of the manufacturers I was present when their analyst made a second and a third examination of the samples from the cask containing the fluid under dispute and by their very kind permission I am allowed to describe the method of testing adopted by them, which is as follows:—

Method of testing 35 per cent. disinfecting fluid.—100 cubic centimetres of the fluid to be tested is placed in a small flask and enough dilute H_2SO_4 (one part H_2SO_4 in three) added to neutralise it. About nine cubic centimetres will be found to be necessary. It is warmed and well shaken, then put into a separator and then, after standing a few minutes, the lower aqueous portion is drawn off. The increase in volume being noted, it is neutralised with dilute caustic soda (of a specific gravity of 1·210) and the volume of the resulting pyridine bases read. Subtract this from the increase in volume and the amount of water (first portion) is obtained. The oily upper portion is then run into a Würtz flask fitted into Liebig's condenser and distilled up to 270° C. To prevent bumping some pieces of marble or limestone are put into the flask before commencing to distil. When all the water is distilled over (which may be noted by the cessation of frothing) the distillation is slackened for a moment to allow of the water being read. This, added to the first portion, gives the total water. The distillation then goes on up to 270° C. and the tar oils come over with the acids in solution. The total distillate is then placed in a small flask and washed with three washes of dilute caustic soda, (1) of a specific gravity of 1·125 (30 cubic centimetres), (2) of a specific gravity of 1·210 (20 cubic centimetres), and (3) of a specific gravity of 1·210 (20 cubic centimetres). The distillate is warmed and well shaken with each wash, then put into a separator, and after standing a few minutes the lower portion being drawn off each time into a graduated cylinder (stoppered) in which it is neutralised by the careful addition of dilute H_2SO_4 and in which the tar acids obtained may be read. A further wash of 20 cubic centimetres dilute caustic soda (1·210) may be given to see if all the tar acids are removed and after this a wash of 15 cubic centimetres of dilute H_2SO_4 is put to the oil, warmed and shaken, separated into a graduated cylinder, neutralised with soda (1·210) and the resulting pyridine bases added to those formerly obtained give the total percentage of pyridine bases in the fluid.

Method of testing disinfecting powder.—50 grammes of the powder are weighed into an ordinary retort and directly distilled into a 100 cubic centimetre graduated measure (or a 50 cubic centimetre measure will do). Care must be taken to apply the heat gradually at first, so as not to crack the retort. First, the water distils off, and secondly, the phenols. The heating is continued as far as possible and the resulting volume of water and phenols are read in the measure. Before finally discontinuing the distillation it is usual to shake the powder in the retort up well and again heat. Then the percentage of phenols in the powder is to the amount read as 10·5 : 10. 10 : 10·5 :: amount of cubic centimetres of phenols read × 2 : percentage of phenols in powder by weight. This is necessary as the specific gravity of phenol is about 1·050. This method is not applicable to a powder in which the phenols are combined with the base, or to a powder having as a base peat or any other substance which can be destructively distilled. To find if the distillate be phenols or neutral oils dissolve in about seven times its own volume of caustic soda (of a specific gravity of 1·125) when, if phenols, they should dissolve.

In forwarding to you this communication I have not the least pretension of posing as an analyst or as one who has a knowledge of the manufacture of tar products. I have merely mentioned facts which have come before me whilst endeavouring to safeguard the public interests as a public servant and I thought that knowledge obtained in such a manner might be of great use, not only to the medical profession, but to the public at large, more especially as it might prevent litigation should there be any dispute in respect of such kinds of disinfectants between those engaged in the care of the public health and those who manufacture carbolic disinfectants or contract for the supply of such articles. I may say, in conclusion, that the investigations which I have recently made have fully convinced me of the necessity of adopting uniform systems of testing such disinfectants as this communication deals with on the part of all public bodies who employ them. Without this we shall be subject to continual trouble and disappointment.

Bow road, E.

TUBERCLE BACILLI IN MILK, BUTTER, AND MARGARINE.

By H. E. ANNETT, M.D. VICT., D.P.H.,
PROFESSOR KOCH'S INSTITUTE, BERLIN, AND THE THOMPSON YATES LABORATORIES, LIVERPOOL.

IN the midst of the great movement at present occupying the attention and interest both of the profession and the public—namely, the provision of sanatoria and homes for the phthisical—there is some danger of the fact that tuberculosis is a preventable disease being considerably neglected. The human digestive tract plays an important, but probably the most easily preventable, rôle in infection by tubercle bacilli; a rôle, however, insignificant in comparison to that of the respiratory tract, in tuberculosis of adults, but very important and considerable in the case of young children and infants. In view of the most recent experimental work on the question of the presence of tubercle bacilli in milk, butter, and margarine, an apology for again introducing this subject, on which much has already been written, is deemed unnecessary.

TUBERCLE BACILLI IN MILK.

Numerous bacteriological examinations of milk during the last ten years have proved the presence of tubercle bacilli in a greater or less percentage; for example, in Berlin milk by Obermuller[1] to the extent of 61 per cent., and by Petri,[2] also in Berlin milk, only of 14 per cent.—using the method of inoculation of animals as the test. Also Rabinowitsch and Kempner[3] found that 28 per cent. of 25 samples of Berlin milk contained tubercle bacilli.

In the medical officer of health's report[4] to the Liverpool Health Committee on the question of tubercle bacilli in the milk supply of Liverpool 2·8 per cent. of the 144 samples collected from sources within the city were proved to be infective by experiments of Professor Sims Woodhead, Professor Boyce, and Professor Delépine, while 29·1 per cent. of 24 samples taken on arrival from parts of Cheshire, Shropshire, &c., at the railway stations were found to be tuberculous. Similarly Professor Delépine[5] reports of the milk supplies of Liverpool, Manchester, and other parts, 5·55 per cent. of 54 samples collected from town dairies, and 17·6 per cent. of 125 samples of milk from country farms collected at the railway stations proved to be tuberculous. Again, milk collected from 16 Cambridgeshire dairies, a sample from each, was reported by Kanthack and Sladen[6] to have produced tuberculosis in guinea-pigs on inoculation to the extent of 56·3 per cent. of the milk (nine samples).

[4] Report and Brit. Med. Jour., 1897, vol. ii., p. 102.
[5] Brit. Med. Jour., 1898, vol. ii., p. 917.

Professor Boyce, to whom I am indebted for permission to use his results, has carried on numerous experiments during the last two years for the Health Committee of the Corporation of Liverpool. During the year 1898 84 samples of "town" milk, of which seven (= 8 3 per cent.) proved to be tuberculous on guinea-pig inoculation, and 28 samples of "railway" or "country" milk, of which five (= 17·8 per cent.) were infective, were examined, while during 1899 to the end of June, of 75 samples of "town" and 63 samples of "railway" milk 6·6 per cent. of the former and 17 4 per cent. of the latter proved to be tuberculous. These results indicate the effects of better sanitation in the cowsheds, shippons, and dairy premises in large towns, as compared with country places, enforced by local by-laws ensuring better ventilation, spacing, cleanliness, and regular inspection.

The consideration of the relation between the presence of tubercle bacilli in milk and the extent of the disease in the animal yielding that milk adds greater and more important interest to the question. The use of tuberculin for the detection of tuberculosis in cattle seems to be an almost infallible test. The presence of a small tuberculous lymphatic gland has often proved, post mortem, to be the only lesion occasioning the reaction to tuberculin; indeed, some investigators are so sure of its infallibility that they assert that although no naked eye lesions may be detected at the usual examination, a careful search will discover deposits in parts generally never looked at—spinal column, joints, and interior of bones, &c.

In 1880 Bollinger[7] by inoculation experiments found the milk of a cow with tuberculosis of the udder to be infective, as also that of another case of tuberculosis without lesion of the udder. May[8] obtained only one positive result with the milk of six "graped" cows, and Stein[9] four positive results from 14 "graped" cows. Bang[10] of Copenhagen has made numerous experiments. The milks from 63 cows with advanced tuberculosis were proved to be tuberculous only in 14 per cent. Hirschberger[11] asserts from his experiments (20 cases with 11 positive results) that milk may be infective when only a small lesion occurs in the lung. Ernst[12] examined 114 samples of milk from 36 tuberculous cows showing no udder lesion and 28 67 per cent. proved to be infective; Smith and Schröder[13] found the milk infective in two cases out of six tuberculous animals with no udder lesion, and Schröder later found the same in two samples of milk from 31 tuberculous cases. Delépine[14] proved the presence of tuberculosis in the milk of two cases out of six which had reacted to tuberculin and showed clinically more or less evidence of the disease. In these two cases the udders showed lesions microscopically. Later he examined the milk of 24 suspicious udders with results shown in his table reproduced:—

Table showing Results of Milk from 24 Cows whose Udders were Suspicious.

Milk from udders—	No. of samples.	Producing tuberculosis.			
		Actual number.		Percentages	
A. Certainly diseased	10	5	6	50 0	31·5
B. Probably diseased	9	1		11·1	
C. Healthy	5	—		—	—
Total	24	6		—	—

Rabinowitsch and Kempner's[15] researches are most complete. 15 cows were tested with tuberculin giving a distinct reaction. Three months later samples of their milk were tested and that of 10 of them (66 6 per cent.) proved to be tuberculous. At the time the milk was taken, and previously, clinical examinations of the animals were made and in cases of death post-mortem examinations. The results were as follows: (*a*) Only one cow showed distinct tuberculous udder lesions clinically (besides lung symptoms); her milk (two samples) proved to be infective. (*b*) One cow showed, microscopically only, tuberculosis of the udder (clinically and post mortem advanced disease of organs); the milk was found to be tuberculous. (*c*) Three cows showed advanced general tuberculosis, the udder histologically exhibiting chronic interstitial inflammation without tuberculous deposits; the milk of all three was found to be tuberculous. (*d*) One cow with lung lesions and some emaciation; the milk was found to be tuberculous. (*e*) One cow showed symptoms of commencing lung lesions; the milk proved to be tuberculous. (*f*) One cow on first examination was suspected; on two subsequent examinations the animal seemed normal; the milk was found to be tuberculous. (*g*) Two animals showed no symptoms on three examinations extending over a period of five months, but their milk proved to be tuberculous. (*h*) Four others, three showing clinical signs, and one none, gave non-tuberculous milk (four, two, two, and two samples respectively). (*i*) In one other case, exhibiting post mortem acute and chronic lesions, the inoculation experiments on guinea-pigs failed from the presence of a pathogenic coccus. Therefore, omitting the last case, 10 out of 14 animals (71·4 per cent.), all of which had reacted to tuberculin, yielded tuberculous milk. More experimental work is evidently desirable, but one must clearly infer from these experiments that any animal which reacts to tuberculin indicating lesions which, may be, cannot, even by repeated clinical examination, be detected, is capable of giving milk, which will produce tuberculosis in the guinea-pig on inoculation.

In contrast to Rabinowitsch's results Ostertag[16] concludes, from experiments with the milk of 50 animals which reacted to tuberculin, but showed clinically no sign of disease, that the milk of such animals is absolutely non-infectious for guinea-pigs.

TUBERCLE BACILLI IN BUTTER.

It has been proved by many authors that butter made from tuberculous milk was also infective, and by Heim[17] and Gasperini[18] that tubercle bacilli live and keep their virulence in butter for a period of even 12 days.

Brusaferro[19] found virulent tubercle bacilli in one sample out of nine; Roth[20] in two samples out of 20; Schuchardt[21] only in one out of 42 samples; and Gröning[22] in eight (47 per cent.) out of 17 samples.

From the results of experiments by Rabinowitsch[23] it is now doubtful whether the animals in the above-mentioned experiments (references 19 to 22) were infected with Koch's bacillus tuberculosis. She examined 30 samples of butter from Berlin and 50 from Philadelphia and *in no single case* found bacilli "which by means of culture and the pathological results of guinea-pig inoculations could be pronounced as identical with Koch's bacillus tuberculosis," but "23 samples (28·7 per cent.) produced changes which, both macro- and micro-scopically, resembled those of tuberculosis, but which by more extensive and exact examination could be distinguished with ease." Other authors have described similar pseudo-tuberculosis organisms—Petri[24] in milk, Moëller[25] in milk, in "Timotheus" grass, and in fæces of cattle. The characteristics of Rabinowitsch's micro-organism are as follows. It is immotile and in form closely resembles the bacillus tuberculosis. The bacilli generally occur singly and are often slightly curved, but when growing rapidly in tissue bacilli are often found lying parallel. Sometimes they form long unbranched threads, and sometimes are divided into short pieces. The bacilli are somewhat thicker than bacillus tuberculosis and often show a club-shaped swelling on one side. Spores are not formed, but one portion of the bacillus stains often more intensely than the rest. The bacilli stained by many methods of staining tubercle bacilli cannot be distinguished from the latter; only by the employment of very dilute watery solutions of methylene blue could any distinguishing feature be observed—viz., that bacilli from a culture of bacillus tuberculosis stain only at one spot, the rest of the bacillus remaining unstained, while in the case of bacillus pseudo-tuberculosis the whole bacillus stains faintly and generally uniformly, seldom showing a more deeply stained part.

Cultural differences, however, occur. On agar the bacilli taken direct from an infected animal produce visible colonies on the second or third day. At first the agar surface is covered with a thick, moist, creamy layer; in old cultures by a folded membrane often orange- or copper-coloured. After repeated passages through animals cultures on agar or glycerine-agar show a dry, brittle, crumpled membrane resembling that of bacillus tuberculosis. In plate cultures the deep colonies are grey in colour, round or oval, and uniformly granular. On the surface colonies are better developed, have a uniformly granular grey centre, and a clear wavy outer zone; the surface of the colony is often dry and conical. On butter agar in fresh cultures the colonies are small, white, and dry, later spreading over the whole surface and becoming yellow or copper-coloured. On potato a luxuriantly growing, moist, grey layer is formed. In gelatin growth proceeds very slowly at ordinary room temperatures, colonies becoming visible on the third day. In broth, and especially in glycerine broth, growth is rapid, forming in two or three days a folded membrane on the surface, the broth remaining clear, the culture closely resembling that of bacillus tuberculosis. Broth cultures are distinguishable from those of bacillus tuberculosis by their characteristic odour, being unpleasant and ammoniacal, that of bacillus tuberculosis being agreeable and resembling the odour of flowers. A small quantity of indol is formed in broth cultures, which is not so in bacillus tuberculosis cultures. Milk is not coagulated and on the surface is an abundant yellowish-red layer which clings firmly to the glass. On albumin-free colourless media a growth appears in two or three days, becoming in ten days a thick yellow folded membrane, bacillus tuberculosis in the same time on such media forming a thin layer just covering the surface and just beginning to fold. The presence of fat in these bacilli can easily be demonstrated as in the case of bacillus tuberculosis.

Pathogenic properties of bacillus pseudo-tuberculosis.—The following are the post mortem appearances observed in a guinea pig killed three or four weeks after intra-peritoneal injection of butter containing the bacillus pseudo-tuberculosis. There is a slightly distended abdomen; also peritonitis with adhesions varying in nature from delicate fibrinous bands to firm connective tissue. The peritoneum and mesentery are studded with nodules. The mesenteric glands are swollen and may contain purulent or caseous matter. The liver is covered with nodules and patches which may be raised above the liver substance or may penetrate into the liver parenchyma. The spleen is sometimes only enlarged, at other times thickly studded with nodules. The kidneys show yellowish patches. The lungs are covered with small transparent nodules which do not penetrate into the lung tissue. The sternal lymphatic glands are swollen, but show no caseation. Numerous bacilli can be demonstrated in these lesions. Many animals after injection show considerable signs of illness during the first 14 days with diminution in weight and then recover. Pure cultures of this bacillus are only pathogenic for guinea-pigs (but not always); rabbits and white mice are immune. After intra-peritoneal inoculation of guinea-pigs some die in from four to eight weeks with considerable emaciation and show the following post-mortem appearances; others survive. At the seat of inoculation there is a purulent infiltration containing the characteristic bacilli; also peritonitis varying in intensity from a flocculent fibrinous exudation to strong connective tissue adhesions. The mesentery is studded with small nodules; the glands are enlarged but not caseating; there are patches on the liver, and miliary nodules throughout an enlarged spleen. The thoracic cavity and organs are often almost exempt from lesions. Infected animals do not react to tuberculin. Histologically the nodules in the liver and spleen consist of a collection of lymphoid elements with but very few epithelioid and multinuclear cells. The bacilli are found in the middle of a young nodule, towards the periphery if caseation has commenced. The typical giant cells of tuberculosis do not occur. More often—especially after inoculation with butter containing the pseudo-tuberculous bacilli—the nodules appeared to consist of a central necrosed portion surrounded by leucocytic infiltrated area.

TUBERCLE BACILLI IN MARGARINE.

Margarine was first prepared by M. Mège Mouriès.[7] In his process 1000 kilogrammes of ground fat from freshly slaughtered cattle is mixed with 300 kilogrammes of water, one kilogramme of potassium carbonate, and two sheep's or pig's stomachs cut into pieces, and is heated at 45° C. by steam for two hours. The fat rises and, after being skimmed, is run off and heated at from 30° to 40° C. with 2 per cent. of salt, the clear fat being then poured off from the sediment and cooled at from 20° to 25° C. The granular solid product is cut into pieces, packed into linen, and exposed to hydraulic pressure at about 25° C. with the production of a solid cake of stearin and a liquid oleomargarine, which is passed through cylinders and washed by a shower of water. Of the melted oleomargarine 50 kilogrammes are mixed with 25 litres of cow's milk and 25 kilogrammes of water in which has been macerated 100 grains of finely ground mammary gland of the cow. Annatto is added and the whole churned for about two hours and the product kneaded and washed.

In the method employed in the United States, Austria, and some parts of Germany pepsin is not added, the original finely ground fat being subjected to a temperature below 50° C. for some time. The oleomargarine is mixed with sour milk and a small quantity of bicarbonate of soda and annatto and is churned. After about 15 minutes it is cooled in ice and then kneaded to eliminate the water, then returned with more sour milk and is ready for sale. In Holland the oleomargarine is melted at about 50° C. and is mixed with the requisite amount of milk and of the best Kampen butter and earthnut (arachis) and other oils (cotton, palm, cocoanut, &c.) to lower the melting-point to that of butter. The Kampen butter is prepared specially for this manufacture from an unskimmed mixture of milk and cream and is preferred on account of its powerful flavour which, though unpleasant alone, imparts a pleasant flavour to the margarine.

Hence margarine may be infected in three ways—(1) from the original cattle (tubercle bacilli survive even a temperature of 55° C. for almost four hours); (2) from the butter and milk added; and (3) from contamination during manipulation (phthisical workmen, &c.). Few researches as to the presence of tubercle bacilli in margarine had been done before the year 1899. Morgenroth,[16] of the Hygienic Institute, Berlin, early last year examined 20 samples of margarine and in nine cases proved the presence of virulent tubercle bacilli of Koch—a very large percentage (45 per cent.).

In October, 1898, in Berlin I commenced researches on this question. 36 samples of margarine were collected from shops in different parts of Berlin. Two guinea-pigs received 5 cubic centimetres each from each sample intraperitoneally, the margarine having been just melted at from 45° to 50° C. and injected semi-fluid. Of the 36 samples 21 caused death of both guinea pigs inoculated within 10 days; nine others caused the death of one only of the pair—from peritonitis or septicæmia. So that 15 samples only could be considered, nine with one animal each, six with two. These were all killed some eight or 10 weeks after inoculation, but with one sample only, and that in both the guinea-pigs injected, could there be found any lesion indicating the presence of tubercle bacilli. In these were nodules on the mesentery, containing caseous material; enlarged, purulent mesenteric glands, the intestines and organs were adherent to each other and to the abdominal wall, the liver was enlarged and studded with several dirty yellow patches penetrating into the liver tissue, the spleen was adherent but apparently normal (it was enlarged in one case), and the lungs were dotted on their surfaces with small transparent nodules. The lymphatic glands and nodules on the liver contained bacilli in large number staining by Ziehl-Nielsen's method. Cultures failed because of rapid overgrowth of accompanying micro-organisms. Subcutaneous inoculation into guinea-pigs from the lymphatic glands and liver nodules gave rise to abscesses which evacuated and healed, bacilli staining by Ziehl-Nielsen being demonstrated in the pus. These animals, some weeks after, showed no further lesion. In ns of the nodules in the organs of the original guinea- the *typical* tuberculous characteristics (giant cells and elloid cells) failed. The lesions were therefore probably sioned, not by Koch's bacillus tuberculosis, but by organism identical or similar to that described by inowitsch and detailed above.

---

[16] Hygienische Rundschau, November, 1899.

n Liverpool early in 1899 the experiments were con- ned with 13 samples collected from various shops in the y. Subcutaneous inoculation was practised, two guinea- gs for each sample. In this case only two guinea-pigs died ithin 10 days—so that two samples had only one animal ach. Out of these 13 samples only one proved to be tuber- ulous, the guinea-pig exhibiting post mortem the typical characteristics, both macro- and micro-scopically, of real tuberculosis. Inoculations from the lesions subcutaneously were followed by typical tuberculosis in guinea-pigs. Thus out of a total of 28 samples, 15 of Berlin and 13 of Liverpool margarine, only one proved to contain virulent bacillus tuberculosis of Koch, and that in a sample from the latter city.

I wish to take this opportunity of thanking my late colleagues at Professor Koch's Institute for their great courtesy and kindness towards me during the 18 months when I worked among them, and particularly Professor Koch, Professor Pfeiffer, Professor Brieger, and Professor Frosch for their help and advice during my researches.

Liverpool.

THE FEASIBILITY OF CARRYING OUT THE OPEN-AIR TREATMENT OF CONSUMPTION AT THE PATIENT'S HOME;

WITH AN ACCOUNT OF A SUCCESSFUL CASE.

By T. A. SOMERVILLE, M.R.C.S. ENG., M.O.H.,

AND

EUGENE S. YONGE, M.D. EDIN.,
HONORARY ASSISTANT PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.

THE statement recently made by a distinguished physician[1] that in 95 per cent. of the cases of phthisis seen by the medical practitioner the patients are unable to afford treatment away from their homes, does not appear to us to be very wide of the mark. And in addition to the item of expenditure there are, amongst other disabilities which bar the way to effective treatment, those salient ones of severance from home; the cessation, in the case of the bread-winner, of the family income; and the depressing influence, to some temperaments, of an environment of sick people; all of which render it advisable to possess a substitute for the treatment by sanatorium or sea-voyage when such methods are impracticable.

following ca
acute

him a great deal of work and worry. been, in consequence, rather "burning the candle at both ends." On examination there was some loss of resonance and of expansion at both apices, with increased vocal fremitus, bronchophony, harsh breathing, and prolonged expiration at the left apex. There was a faint systolic mitral murmur and accentuation of the pulmonary second sound. The temperature averaged 102° F. in the morning and 103° in the evening. The larynx was in a condition of catarrhal inflammation, and microscopic examination of the sputum revealed large numbers of tubercle bacilli. The cough, pyrexia, and other symptoms continued without much change for about three weeks. On June 29th the patient was seen by us in consultation and we considered the case to be one of early acute pulmonary phthisis with a catarrhal laryngitis, possibly pretuberculous. The condition of matters was explained to the patient and the various methods of carrying out the open-air treatment were discussed. He was extremely unwilling to take a voyage or to leave his home for any length of time, as he felt that the neglect of his business, which was a personal one, would result in serious trouble, and both he and his friends were so much opposed to the usual sanatorium treatment that the idea was relinquished.

Creasote, maltine, and an inhalant were prescribed; a liberal diet was enjoined and the patient was advised to spend as much time as possible in the open air. His house was, fortunately, situated in the country, at a village about 12 miles from the city where he carried on his business. Although in no sense a health resort, the climatic and sanitary conditions of the village are good. The death-rate is 14 per 1000 and there are few indigenous cases of phthisis. The rainfall for 1899 was 26 25 inches and there is seldom any fog. The patient's residence, which is built on sandy soil, faces south-east. On August 9th, after adopting the modified treatment indicated above for about six weeks, the patient was again seen in consultation; and the condition then reported was that the cough, night-sweats, and anorexia had all considerably lessened; the nocturnal temperature had fallen to 99° and a gain in weight of 16 pounds had accrued. An examination of the lungs, however, showed that the tuberculous process was still active. There were signs of softening at the right apex and at the right base there was a small patch of pleurisy. The left apex and the larynx were practically in *statu quo*. It was therefore suggested that he should carry out the open-air treatment quite systematically and that it should be supplemented by moderate over-feeding and graduated exercise under our supervision. The method then adopted was to spend at least six or seven hours daily in the open air, either walking about slowly or driving, or sitting in the garden. The "lung gymnastics" recommended by Dettweiler were frequently practised. If the weather were wet the patient sat in a shelter (summer-house) facing the south; or if not very rainy he took short walks clothed in suitable garments—which he exchanged for dry ones as soon
as he came indoor—and thick waterproof boots. The
windows in his bed in the sitting-room which he
occupied always re open. His friends at first
to this e soon got
was

second week the digestive organs rebelled somewhat. The patient suffered from gastric catarrh and lost one pound and he also felt generally less well. During the third week the gastric symptoms disappeared and two pounds in weight were superadded. After that time he gained, on an average, one pound per week up to Oct. 13th (about three and a half months from commencing treatment), when he found that he had gained an aggregate of 28 pounds, or an average on the whole time of about two pounds per week. His present weight (Jan. 1st, 1900), seven months after commencing treatment, is 10 st. 11 lb., an increase of 2½ st. in that time.

The total effect of the combined fresh air, the feeding, and the exercise was that, in addition to the gain of weight, the cough and expectoration rapidly and entirely disappeared, the night-sweats vanished, he had no return of the dyspepsia, the temperature kept within normal limits, the larynx returned to its normal condition, and the patient, on Oct. 13th (about two months after commencing the open-air treatment systematically), appeared both subjectively and objectively to be perfectly well. The condition of the lungs at this date was, no abnormal dulness at either apex, expansion good, breath sounds vesicular, and expiration not prolonged. The moist râles had quite vanished. Re-examinations of the sputum have failed to give any evidence of tubercle bacilli. The patient informs us that he spent one of the six months during which he was under treatment at Rhyl in North Wales. He wrote to us last at the end of December, 1899, and reported himself as being perfectly well.

The case described above appears to have been an acute tuberculous broncho-pneumonia, an instance of one of the commoner forms in which phthisis florida, or what is popularly known as "galloping consumption," is met with. The loss of flesh and strength in such patients is very striking, and frequently out of proportion to the physical signs. The temperature is high, the pulse is rapid, and the respirations are increased. There may be repeated chills, as in the instance of our patient; and we suspect that the symptoms noted early in May were attributable to the tubercle bacillus rather than to the organism of influenza. Three points greatly in favour of the method adopted were the incipiency of the disease, the power which the patient enjoyed of securing abundant good food and favourable surroundings in the country, and the intense interest which both he himself and his friends took in the treatment. Perhaps the most serious indictment which has been brought against the home treatment of early phthisis is the absence of that discipline which prevails in sanatoria, and without which it would sometimes be impossible to enforce what may appear to the lay mind as unnecessarily drastic measures. The only remedy for this appears to be the substitution, in a measure, of the authority of the practitioner in attendance for that which would appertain to the director of a sanatorium, were the patient in such an institution, and the early settlement of the rival claims, on the one hand, of the patient's friends and, on the other hand, of the medical man, to conduct the treatment of the case. If the practitioner feels unequal to the task of breaking through the phalanx of lay ignorance and prejudice with which he may be confronted, it appears to us far better to advise that the patient be sent to a sanatorium.

It is possible for any phthisical patient living in the country and possessing a garden in which a small shelter can be erected to carry out the treatment; but he should be under the strict supervision of his medical man who takes the thermometer as his principal guide to the amount of exercise, &c., which the patient is to practise. Daily supervision of this kind was carried out in the case quoted above. The shelter, facing the south, should contain a couch or chair and be provided with moveable curtains or shutters to keep out the cold winds and driving rain. The open-air treatment ought not to be intermittent, but carried on throughout the 24 hours, the windows being widely opened when the patient cannot be out of doors.

'But although the home treatment of consumption will in all probability yield the best results where the pinch of poverty is not felt, it does not follow that the poor are altogether debarred from its advantages.' Osler,[2] in a recent paper, has advocated its employment for the benefit of this class of patient. And whilst he admits that the quality of fresh air in large cities may not be very good, he remarks that it is the best that a large proportion of our patients have to breathe, and it is considerably superior to the atmosphere of the ill-ventilated, over-heated rooms in which the majority of them live. Even for those of the poorer classes who apply at a hospital for consumption when the disease is in its curable stage, there are many weary days of "waiting for beds" when effectual treatment is practically in abeyance, when valuable time is being lost, and the patient is slipping towards the boundary which delimits the possibility of cure. For such as these Osler gives the following directions:—Take the almanack and count off the hours of sunshine. In the winter cut off two hours in the morning and one hour in the evening, and for the rest of the day the patient must be out of doors. If there is no possible arrangement for life out of doors the patient must be put in a room with a southern exposure and the bed moved in the sunshine, with the windows wide open. If there is a balcony or verandah with a good outlook towards the south it should be arranged for the patient; if not, a shelter could be put up in the yard at a very moderate cost. On a well-padded lounge, covered with a couple of thicknesses of blankets, the patient sits or reclines all day. Only on blusterous, stormy, or very rainy days is the patient to remain in the house. No degree of cold is a contra-indication.

We have drawn attention to the case reported above with a view of stimulating the home treatment of consumption in those instances where treatment at a sanatorium—which is preferable if possible—is found to be, for some reason, impracticable; and also with the idea of counteracting the feeling which some of the profession entertain towards the sanatorium treatment, that in the management and cure of early phthisis the axiom *aut sanatorium aut nihil* practically sums up the whole position.

GUY'S HOSPITAL.

A CASE OF SEVERE INTRA-UTERINE HÆMORRHAGE FROM CYSTIC MOLAR PREGNANCY.

(Under the care of Mr. J. H. TARGETT.)

A WOMAN, aged 28 years, was admitted into Guy's Hospital on Sept. 29th, 1898, for swelling of the abdomen and vaginal hæmorrhage. She had had four full-term and normal parturitions and no miscarriages. Her last confinement was on July 15th, 1897, and she nursed the child for about a year. Menstruation returned during the latter part of her lactation and her last menstrual period began on July 1st, 1898. On August 15th she had a sudden hæmorrhage from the vagina and began to be sick, but she had no idea that she was pregnant. The bleeding occurred whilst the patient was at supper and was accompanied with sharp pain in the right iliac region and groin. It recurred at intervals during the night and the next day she was better, but on the third day the hæmorrhage became continuous and the vomiting was frequent. There was no abdominal enlargement at this time, but from the onset of the bleeding until the date of admission the abdomen had steadily increased in size. Micturition was frequent and the bowels were much confined.

When admitted to the hospital more than six weeks after the onset of the hæmorrhage the patient was decidedly blanched and much wasted. The temperature ranged between 99° and 100·5° F. The breasts were very small and lax; they contained no secretion and showed no recent pigmentation. The abdomen was occupied by a large central swelling of the size of a seven months' gestation. It was pyriform in shape, rising out of the pelvis to the level of the ninth costal cartilages, and had a uniform outline. The tumour had an elastic feel and gave a most distinct thrill in all directions, but it hardened on palpation like the pregnant uterus. The loins and epigastric region were resonant, and no fœtal heart-sounds or uterine souffle was detected after repeated examinations. Per vaginam the cervix uteri was found to be softened and the external os patulous, and there was a constant but not profuse discharge of a dark-red sanguineous fluid. The abdominal tumour was directly continuous with the cervix uteri and was therefore without doubt the enlarged body of the uterus. In view of the large size of the uterus, the constant sanguineous discharge, and the absence of all signs of a fœtus a diagnosis of vesicular mole was made.

---

[2] Loc. cit.

On Oct. 1st the uterus was evacuated under an anæsthetic. The cervix was slowly dilated with Hegar's dilators and by degrees two fingers were inserted, but the dilatation was difficult owing to rigidity of the cervix. The body of the uterus felt like a large sac with lax walls and a small rigid orifice. It seemed to be filled with soft blood-clot. By pressure on the fundus the clot was brought within reach of the two fingers in the uterus and thus removed as rapidly as possible. But the uterus did not contract and the hæmorrhage at one time was very profuse and alarming. Much of the clot, however, was dark and had evidently existed in the uterus for some time. The last portion of the uterine contents consisted of typical vesicular mole, recent blood, and fluid. To control the hæmorrhage the flabby uterus was strongly anteflexed over the pubes by bimanual pressure and a hot douche was prepared. The combined effects of kneading, pressure, and heat induced uterine contraction and retraction, and two hypodermic injections of ergotin were then given. The quantity of blood lost could not be estimated, but it must have been very considerable as the uterus reached nearly to the ensiform cartilage and fully three-fourths of its contents consisted of old and recent blood-clot, the rest being cystic mole. It was afterwards found that the cervix had been split rather deeply into the right fornix, which must have occurred during the rapid digital evacuation of the uterus on account of the hæmorrhage, as no instruments were used for this purpose. The rigidity of the cervix greatly hampered the use of the fingers.

The subsequent progress of the case was slowly towards recovery, and during the greater part of a tedious convalescence the temperature ranged between 99° and 100·5°, but it only reached 101° on one occasion. A small cellulitic effusion formed on the right side of the cervix in connexion with the above-mentioned laceration, and this in turn appeared to cause a swelling in the right iliac region which gradually enlarged and extended back into the right loin. It felt distinctly elastic, like fluid, and could be grasped bimanually through the loin suggesting a hydronephrosis on the right side, possibly due to pressure on the right ureter. The involution of the uterus was much delayed, and when the patient went to a convalescent home seven weeks after the operation the fundus uteri was still three inches above the pubes. The right iliac swelling had disappeared and the parametritis was much diminished but the patient was still decidedly anæmic. No suppuration occurred either in connexion with the iliac swelling or the cellulitis of the right broad ligament.

Remarks by Mr. TARGETT.—The occurrence of severe intra-uterine hæmorrhage in cases of cystic mole and the resemblance between this condition and concealed accidental hæmorrhage are not mentioned in the text-books, but Dr. Herbert Williamson has recently drawn attention to the subject in a valuable paper read before the Obstetrical Society of London.[1] He records a case which in many points resembled mine, but the hæmorrhage was less severe. In regard to the differential diagnosis from concealed accidental hæmorrhage he thinks that the absence of the fœtal heart-sounds and of the uterine souffle is very important. I have met with two other cases of cystic mole associated with abundant hæmorrhage into the uterine cavity and in one of these the abdominal tumour had been mistaken for an ovarian cyst, and ovariotomy was about to be performed. In the case mentioned above the thrill obtained from the large abdominal tumour was so perfect that the same mistake might have been made, but was prevented by the detection of intermittent uterine contractions. Though concealed accidental hæmorrhage is more likely to occur in the later months of pregnancy, yet it may be met with in the first half of the period of gestation, and then the clinical symptoms will more closely resemble those of a cystic mole. A patient came under observation recently for severe vaginal hæmorrhage of three weeks' duration. She considered herself to be four months pregnant, but the uterus was fully of the size of a six months' gestation. No fœtal heart-sounds were heard and no part of a fœtus could be felt. The patient was decidedly anæmic. On exploration of the uterus the cavity was found to contain three pints of old and recent blood-clot with a dead fœtus of about four months' development. The diagnosis of cystic mole had been made, but in reality the condition was concealed accidental hæmorrhage with intra-uterine death of the fœtus. It is generally stated that dilatation of the cervix sufficient for the introduction of two fingers will enable the operator to evacuate the uterus; but in the above case the rigid cervix, though admitting two fingers, split rather than dilated on manipulation, and the same thing happened in one of Dr. Williamson's cases. Moreover, with a uterine cavity so greatly dilated and relaxed, the removal of its contents through such a narrow orifice was tedious and difficult and not without risk to the patient from inefficient control of the hæmorrhage. It would have been better if the cervix had been more fully dilated by hydrostatic bags before the operation was begun. As regards mortality I may note that out of six cases seen during the last three years none died directly from the disease, but one of them developed within a few months a typical deciduoma malignum, to which she speedily succumbed.

LIVERPOOL NORTHERN HOSPITAL.

TEN CASES OF MALIGNANT PUSTULE.

(Under the care of Mr. CHAUNCY PUZEY, Mr. DAMER HARRISSON, and Mr. R. W. MURRAY.)

THE great value of excision in cases of malignant anthrax is amply demonstrated by this interesting series of seven cases, although it is possible that the ipecacuanha had some share in the results. The assistance in diagnosis which is afforded by the bacteriological examination of the fluid in the vesicles cannot be over-estimated, and it is, moreover, always advisable to examine the blood for the bacilli as the prognosis depends greatly on the question of the generalisation of the micro-organisms, though cases have been described in which recovery has followed excision even after the bacilli had been discovered in the blood. For the notes of the cases we are indebted to Dr. J. Mandall Coates, late senior house surgeon.

CASE 1.—A tanner, aged 27 years, was admitted into the Liverpool Northern Hospital on March 13th, 1899. The patient had a well-marked pustule, with the characteristic vesicle formation surrounding the central black eschar, situated at the left angle of the jaw. There was considerable swelling all round it extending down the neck and round under the chin. He complained of great difficulty in swallowing and felt very ill. The temperature was 101·8° F. It was stated that four days previously he had noticed in the above situation "a pimple," of which he had taken no notice, and that it had gradually got worse until the date of admission. The difficulty in swallowing had lasted some 12 hours before admission. The fluid from the vesicles on microscopical examination contained the typical bacilli of anthrax in great abundance. Shortly after admission the pustule was freely removed, a circular portion about one and a half inches in diameter being excised. Pure carbolic acid was applied to the cut surface and the wound was packed to prevent hæmorrhage, which was free. The temperature at the time of the operation was 104·2°, but it gradually fell, and on the following morning it was 102·4° and the patient felt very much better. Ipecacuanha powder (five grains every hour) was given and the powder was also dusted on the wound each time it was dressed. From this date onward the patient improved and on the 16th the temperature was normal; on the 22nd the surrounding œdema had almost disappeared and he was discharged on May 15th.

CASE 2.—A tanner, aged 19 years, was admitted into the hospital on April 25th, 1899. In this case the pustule was situated at the back of the neck in the middle line and displayed the same typical characters as that in Case 1. There was a considerable amount of swelling entirely obliterating the hollow behind the neck. The constitutional symptoms were slight and the patient complained only of some stiffness on moving the neck. The fluid from the vesicles was examined, but owing to the specimens being inadvertently destroyed the bacteriological diagnosis was uncertain. Shortly after admission the patient was operated on, the pustule and a portion of the surrounding tissues being freely excised; the cut surface was treated by the application of pure carbolic acid. Ipecacuanha powder internally and externally was ordered. The temperature dropped on the next day, but on the 27th it rose to 104° F. The constitutional symptoms became more marked, there was no improvement on the 28th, signs of pulmonary embarrassment becoming apparent and the œdema extending down the neck. On the 29th his breathing became very embarrassed and tracheotomy was performed, the operation being rendered difficult by the fact that the trachea was displaced very much to the right by the œdema; no anæsthetic was used. The operation relieved his breathing for a time, but he gradually sank and died in the evening.

---

[1] THE LANCET, Oct. 14th, 1899, p. 1019.

Case 3.—A tanner, aged 27 years, was admitted into the hospital on May 22nd, 1899. He had a typical pustule on the back of the right metacarpal phalangeal joint. Four days previously to admission the patient had noticed a small pimple in the area mentioned which had gradually got larger. On admission the temperature was 100° F. There were no constitutional symptoms and the œdema was slight. The pustule with some of the surrounding tissue was excised, the portion removed being of about the size of a crown piece, followed by the free application of pure carbolic acid and the internal and external use of ipecacuanha powder. The patient made a good recovery and was discharged on July 1st.

Case 4.—The patient, a washerwoman, aged 35 years, was admitted into the hospital on June 4th, 1899. The patient had a pustule at the right angle of the jaw. It was typical and its character was confirmed by bacteriological examination. Treatment was the same as in the foregoing cases. She made a good recovery and was discharged in four weeks. She stated that she had first noticed the pustule about three days previously. It was ascertained that she had been washing the clothes belonging to a tanner and it is reasonable to suppose that this was the source of infection in her case.

Case 5.—A tanner, aged 36 years, was admitted into the hospital on May 23rd, 1899. In this case the patient had two separate and discrete pustules, one on the back of the right forearm about its middle and the other on the edge of the lower jaw about two inches to the right of the symphysis. They were typical in character and the fluid from the vesicles in both instances contained anthrax bacilli. The temperature on admission was 98° F. There were no constitutional symptoms. The patient had first noticed the pustule on his arm four days previously, while that on his face he noticed the day after. One point noteworthy in his history was that he had not been working in the tannery for a week before. The treatment was the same as in the other cases and he made a good recovery.

Case 6.—A tanner, aged 22 years, was admitted into the hospital on June 29th, 1899. The site of the lesion was the forehead. The pustule was typical and its character was confirmed by bacteriological examination. He had first noticed the pustule four days previously to his being admitted. The treatment was similar to the foregoing. He made a good recovery.

Case 7.—A tanner, aged 21 years, was admitted into the hospital on July 8th, 1899. In this case the pustule was situated on the front of the left forearm. On examination the fluid from the vesicles was found to contain the characteristic organism. There was also a little above the elbow of the same arm a pustule similar in appearance but very much smaller. The treatment was on the same lines as that of the other cases. He made a good recovery.

Remarks by Dr. Mandall Coates.—Rarely in this country is anthrax seen in human beings showing an epidemic-like character as it did in these cases and its occurrence is noteworthy. Two tanyards were involved, the source of infection being some hides imported from China. Once such infected hides have undergone all the processes necessary in the manufacture of leather it is apparent that the tanyard will be dangerous for some time to come, even if the infected hides are removed, and the possibilities of infection to individuals working in the yard are by no means remote. The advisability of enforcing regulations as regards personal cleanliness, thorough washing, and changing of the working clothes is shown in Cases 4 and 5. In the former case the patient had never been in a tanyard in her life and in the latter the patient had not been working in the yard for a week, but had been wearing his working clothes. Counting the cases which were treated in other institutions there were at least 10 altogether, of which four were fatal, and these were amongst the first to come under notice. The time between the patient first noticing the pustule and admission to hospital was generally either three or four days. The constitutional symptoms were more especially marked in the earlier cases which were fatal, and the slight symptoms in the later cases seemed to point to a diminution in virulence of the organism. As regards the use of ipecacuanha its use in the above cases may have been beneficial, but I think we must rely much more on early recognition of the lesion and free excision. Certainly in one case (Case 6) in which its administration was delayed for two days it had a beneficial effect on the temperature. As to the diagnosis, in none of the cases was it doubtful, and it can always be confirmed in five minutes by microscopic examination of the fluid in the vesicles. This means of diagnosis was used in all the above cases and in six of them it afforded absolute proof.

Note.—Since the above was written three more cases have been admitted. Two of them were men working in the tannery referred to; the third case was that of a woman whose occupation was wool-sorting. In these cases the same line of treatment was adopted and they have all recovered, thus making 10 cases with nine recoveries and one death.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Bacteriology of Venous Thrombi.—Mycotic Tumour from a Horse.—"Spontaneous" Carcinoma.—Experiments with the Toxins of the Pneumococcus.—Exhibition of Specimens.

A meeting of this society was held on Jan. 16th, Dr. **Sidney Coupland**, the Vice President, being in the chair.

Dr. **Coupland** referred to the absence of the President Mr. Watson Cheyne, on account of his departure for South Africa.

Mr. W. **Pakes** read a paper on the Occurrence of the Bacillus Proteus Vulgaris in a Venous Thrombus. He described a case of thrombosis of the right and left iliac and femoral veins occurring in a patient suffering from phthisis and tuberculous enteritis. The clot in the left iliac vein was examined post mortem and a pure culture of the bacillus proteus vulgaris was obtained therefrom. In spite of the fact that this organism was frequently associated with post-mortem decomposition he did not think that this would explain its presence in the case he described, since these organisms were present in the clot in considerable numbers without any obvious decomposition. He pointed out that an organism like the bacillus proteus vulgaris, which was not pathogenic to a human subject in good health, might become so to a patient whose vitality had been reduced by a wasting illness such as phthisis. He thought that in view of the slight knowledge which we possessed concerning the causation of thrombi it would be well if every case of thrombosis could be examined bacteriologically.

Dr. T. G. **Stevens** gave an account of the Bacteriological Examination of a Thrombosed Ovarian Vein following Hysterectomy. The case was one of subacute septicæmia following abdominal hysterectomy. The right ovarian vein was found to be thrombosed from the ligature to the vena cava. Cultures were made, with every precaution against possible contamination, in broth from the breaking-down clot in the vein. The broth culture, after plating on gelatin, showed colonies of the bacillus coli communis group and the bacillus pyocyaneus. The case was brought forward in the hope that when thrombosis occurred in accessible sites more bacteriological examinations of the thrombus might be made. Such examinations, it was hoped, might be an aid to the surgeon in treating cases of thrombotic pyæmia.

Mr. **Alexander G. R. Foulerton** showed a Mycotic Tumour which had occurred in the Maxillary Sinus of a Horse. The tumour was of irregularly oval shape, measuring 10 centimetres in the longer and 8·5 centimetres in the shorter diameter. It consisted of a central core of soft caseous material enclosed within a mass of dense fibrous tissue, the latter measuring from 2 to 4·6 centimetres in thickness. The core contained a large quantity of the mycelium of a mould fungus. The pathogeny of the tumour was supposed to be as follows. The dense outer fibrous layer probably represented the overgrown wall of a suppurating cyst which had been connected with the fang of a carious tooth. The caseous core represented the inspissated contents of the cyst cavity which had been infected by the mould fungus from the mouth. The mycelium was arranged in star-shaped masses; individual threads differed considerably in their thickness; there was no evidence of sporulation. The mycelium stained well by the ordinary aniline dyes, but not by Gram's method. As there had been no opportunity of making cultures it was impossible to give an opinion as to the exact species of the fungus. It was, however, probably not streptothrix actinomycotica, the common ray fungus of horses and cattle. Nor could it be confounded with the aspergillar moulds which also infected horses. From the nature of the specimen it seemed clear that the fungus had existed within the tumour during the life of the animal and did not merely invade the tissues after death. Mr. Foulerton concluded by asking if any of the members could throw light on the nature of the growth.

Mr. S. G. **SHATTOCK** exhibited a specimen of "Spontaneous" Carcinoma of the Uterus in the Rabbit. Histologically the growth consisted of a columnar-celled papilliferous carcinoma and it affected both the uteri. The mucosa between the many growths was papillary and from such areas the origin of the carcinoma could be traced. There were a certain number of peritoneal metastases. The chief interest of the specimen lay in its bearing upon the experiment recorded last year by Dr. Lambert Lack. This experiment consisted in exposing the ovaries in a rabbit, scraping them, and closing the abdominal wound; the animal, after remaining well for 12 months, then showed signs of abdominal carcinoma and was killed. Many peritoneal nodules were found of columnar-celled carcinoma and the thoracic viscera were involved. Dr. Lack's conclusion was that the dissemination of normal epithelial cells from the ovary had led to the growth of the tumours, and in arriving at this he had been largely influenced by the fact that Professor J. McFadyean had not seen or heard of carcinoma in the rabbit. The condition of the uterine mucosa in Dr. Lack's case was precisely as in that exhibited and there was, moreover, a growth as large as a cherry in the uterine wall itself. Mr. Shattock contended, therefore, that unless the same result could be repeated it must be regarded as a coincidence. The injury inflicted on the ovary also complicated the experiment and he had modified it on a series of rabbits by the method of intra-peritoneal injection of scrapings of ovary, &c., suspended in warm sterilised salt solution. The dissemination of peritoneal papillomata after rupture of a papilliferous ovarian cyst was not a just comparison since normal characters could not be safely ascribed to such epithelium. The contagiousness of the warts that occurred in the mouths of dogs had been proved by the experiments of Professor J. McFadyean and Mr. F. Hobday. These experiments showed also that an immunity to infection might be acquired by inoculation and Mr. Shattock suggested that the disappearance of peritoneal papillomata following removal of the ovarian growth might be due to a similar acquired immunity. When the case of normal epithelium was considered such experiments as were forthcoming told the other way. The intravascular injection of gland emulsions by Lubarsch and his pupils Krückman and Lengemann was in no case followed by the growth of tumours; neither was the traumatic detachment of tissue, whether the fragments were allowed to remain *in situ* or transplanted to another animal of the same species. Though the blood stream was chosen, yet the metastasis that took place both in sarcoma and carcinoma by this stream showed that if the emboli possessed the right characters the growth of tumours followed. The epidermal cysts of the palm and palmar aspects of the fingers that arise from the traumatic dislocation of epidermis into or beneath the substance of the corium furnished an excellent object-lesson of what ensued in such cases. He had referred to this on the occasion on which Dr. Lack had exhibited his specimen in July of last year. Amongst the same class of phenomena must be ranged the multiple formation of cysts which may follow the rupture of an ovarian dermoid. Here, again, there ensued a production of simple circumscribed cysts and not a carcinomatous infection of the peritoneum such as should arise were the mechanical hypothesis of the origin of carcinoma a true one.—Dr. **SIDNEY COUPLAND** remarked that the facts to which Mr. Shattock had drawn attention were of the greatest interest and the inferences deduced had certainly carried conviction to his mind. Certain epithelial cells seemed to be endowed with the property of malignancy. The subject of the infectivity of warts was also one of great interest in view of the remarkable way in which they appeared and disappeared spontaneously.—Mr. C. A. **BALLANCE** thought that it was a fact now generally recognised that the action of normal epithelial cells when transplanted into other tissues or lymph spaces was limited. They only had a certain power of development, but when malignant their power of growth was unlimited. What was this property of malignancy? Dr. Lack's experiment did not settle the question, but in the contents of the Graafian follicle they had something quite special, for if these epithelial cells came in contact with (became infected by) certain other cells, the spermatozoa, they at once took on that most remarkable power of growth which resulted in the fœtus. Almost the same thing might be seen in cancer cells which took on unlimited growth (terminated in short only by the death of the individual) when they became infected by the hypothetical microbe of cancer. He (Mr. Ballance) agreed with Mr. Shattock that Dr. Lack's experiment was nothing more than a remarkable coincidence. An experiment required to be repeated again and again to be of any use. He and Mr. Shattock had repeatedly, in the course of their experiments, found that what they had taken for a law was only an incident.

Dr. A. G. **AULD** read a paper embodying the Results of Experiments with the Toxins of Pneumococcus performed in the Research Laboratories of the Conjoint Board. Nearly 200 animals, chiefly rabbits, were experimented on during a period extending over two years. The first series of experiments related to the production and action of toxins found in the organism. To counteract the effects of the lactic acid produced by the coccus, which inhibited its further growth, various media which were described were used. Side by side with the animals inoculated with virus "control" animals were always kept. Toxins of gradually increasing virulence and cultures of different generations were injected in the different series of experiments which were fully described by Dr. Auld. The most notable result of these experiments was undoubtedly the increased sensitiveness to the pneumococcus produced by inoculation of its toxins, in rabbits at least. Under all circumstances of dosage this super sensitiveness was manifest, and consequently any attempts to immunise in this way seemed to be contra-indicated. These results, however, harmonised to some extent with what had been found in the case of plague and other toxins. This harmful action of the toxins would indicate that the intra-cellular poisons of the bodies of the micro-organisms were probably the most suitable immunising agents, and this view was borne out by the experiments of Foà and Scabia,[1] who stated that a watery glycerine extract of the dead bodies of the pneumococci formed a much better minimising medium than the diluted virus itself. The lethal dose of toxin obtainable in these experiments was about one-hundredth part of the weight of the animal, which corresponded with the lethal dose of the filtered extract of the blood and tissues of rabbits dead from pneumococcal infection, as was found by Isaeff. The occurrence of fore-leg paralysis in two cases was noteworthy, and, as far as Dr. Auld was aware, had not hitherto been observed. It would appear that the poison had a relative affinity for the nerves and their centres supplying these parts. Dr. Auld, in conclusion, desired to acknowledge the help and participation which he had received from Dr. Cartwright Wood in these researches.—Dr. J. W. H. **EYRE** wished to ask Dr. Auld what was the source of the pneumococcus used in these experiments and what were the features by means of which he established its identity, since it was important to establish its identification. Another point he wished to refer to was the reaction of the media in which the cultures were grown; it was not sufficient that these should be neutral, they must be decidedly alkaline to grow the pneumococcus successfully.—Mr. W. **PAKES** remarked that this increased susceptibility or hyper-sensibility of an animal produced by the introduction of pneumococcus toxins was a somewhat novel result in his experience and he would like to know in what other organisms it obtained.—

---

[1] Gazetta Medica di Torino, 92; 13, 14, 16.

Dr. **AULD**, in reply to the first speaker, said the organism was a capsulated diplococcus whose identity was beyond dispute. As regards the alkalinity of the media, this was insured by the layer of chalk at the bottom of the flask, which was occasionally stirred or shaken, a fact to which he had already made reference. It was to this high alkalinity that he attributed the extreme virulence of some of the growths which he had obtained. The hyper-sensitiveness of the animals produced by the toxins was certainly a remarkable result, but it was to be found under certain conditions in connexion with plague, diphtheria in guinea-pigs, and he believed with tuberculin under certain circumstances.

The following card specimens were exhibited:—

Dr. E. M. **CORNER**: A Supra-patellar Sesamoid Bone.

Dr. H. A. **LEDIARD**: (1) A Loose Cartilaginous Elbow-joint; and (2) Hydatid Cyst from Muscle.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 12th, Sir R. **DOUGLAS POWELL**, the President, being in the chair.

Mr. J. **HUTCHINSON**, jun., narrated a case of Subperiosteal Resection of the Os Calcis, followed by complete reproduction of the bone. The patient was a lad who at the age of 15 years became the subject of acute periostitis and osteitis of one os calcis. At the end of five weeks from the onset of the disease, after the sinuses had been explored, the os calcis was found to be necrosed, and three weeks later the whole bone was removed, taking care to leave the periosteum, in which new bone was beginning to form. After this the patient, who had been extremely ill with high fever, began to improve, and now at the end of ten months he was walking well with the aid of a stick. There was a well-shaped firm heel on which the patient could stand upright with perfect ease.—Mr. **HERBERT PAGE** remarked that removal of the os calcis was not a new operation. It was done by his father in 1848, and he had in his possession a plaster-cast of a man's foot on whom the operation had been performed in that year. Mr. Hutchinson's case was a very interesting one, the chief importance lying in the fact that the os calcis had been so completely reproduced.—Mr. J. **HUTCHINSON**, jun., in reply, said that he did not wish to lay claim to any originality, but he thought that the case was one of sufficient rarity and interest to bring forward as showing what favourable effects could be produced by subperiosteal resection of the os calcis.

Mr. J. R. **LUNN** showed two cases of Diplegia Facialis, one occurring in a man and the other in a woman. Both were due to double ear disease. Both sides of the face were quite paralysed and immobile, the skin was smooth, and it was impossible for the patient to close the eyelids in either case. All the muscles showed the reaction of degeneration, the masseters alone being unaffected. Both patients were absolutely deaf and the membrana tympani were perforated. The woman at first had been quite unable to taste anything, but lately the sense of taste had returned. In the man, who had been paralysed for a longer time, taste was wanting at the tip and sides of the tongue but was preserved elsewhere. There was no paralysis of the palate in either.

Mr. **LUNN** also showed a case of Congenital Dislocation of the Right Hip occurring in a child, aged five years. The family history was not obtainable. The dislocation was on the right side. The patient stood with the right foot markedly everted; her gait was "waddling," but this was not so marked whilst running. An appreciable amount of lordosis was present, but it disappeared in the recumbent position. The upper border of the right trochanter was above Nelaton's line. There was a limp on the affected side, and the right shoulder was lower than the left. There was no appreciable wasting of the gluteal muscles. Traction caused a disappearance of the shortening which amounted to three-quarters of an inch. The head, neck and shaft of the bone were slightly atrophied.—Mr. J. **JACKSON CLARKE** asked what treatment it was proposed to adopt in the case, which was certainly one of a moderate degree of congenital dislocation. There was a considerable limitation of abduction in these cases which was inconvenient. He thought well of Laurenzi's bloodless method of treating such cases. The results of this method he had found very satisfactory.

Mr. **LUNN** also showed a case of Paroxysmal Hæmoglobinuria occurring in a child aged six years. The patient was admitted on Nov. 28th, 1899, for hæmaturia. Her urine had been examined on a great many occasions, no reaction for blood being obtainable until Dec 9th. The urine was blood-coloured when exposed to the cold, but a positive guaiacum and ether test was seldom obtained. She had not had scarlet fever. The patient had never been known to pass any calculi per urethram, but was said to have once had "gravel." Mr. Lunn had seen her sister, who was evidently suffering from syphilitic choroiditis and interstitial keratitis.—Mr. W. G. **SPENCER** referred to a case of paroxysmal hæmoglobinuria under his care in which gangrene occurred after a horse bite. There was a considerable degree of arterial tension in that case. He also referred to the association of such cases with Raynaud's disease. These cases sometimes ended in uræmia, and at any rate the prognosis of cases associated with high arterial tension was generally grave.—Dr. A. F. **VOELCKER** thought it was very interesting to note the association of syphilis with the disease in the child. In three cases of paroxysmal methæmoglobinuria which he had seen there had been this association and in one of them, that of a child, the syphilis had been acquired. Another interesting point in Mr. Lunn's case was the blood changes. In some cases of methæmoglobinuria he had noticed in the blood that the corpuscles did not run into rouleaux, but that they seemed to show an unduly adhesive power so as to form long snake-like chains under the microscope. In all three cases of methæmoglobinuria associated with syphilis, he had noticed this change.—Dr. G. A. **SUTHERLAND** remarked on the occurrence of albuminuria in these cases. Some held that intermittent albuminuria and paroxysmal hæmoglobinuria were different stages of the same disease—the former being the initial condition. He would like to know whether there had been any oxalates in the urine. This was often a striking feature in these cases and it persisted after the hæmoglobinuria had passed off.—Mr. **LUNN**, in reply, said that the child was one of a family of 24. She was all right unless she was exposed to cold; then the temperature would rise to 99° or 100° F., the patient would become somewhat collapsed, and blood would be passed in the urine. There was no history of any symptom of Raynaud's disease in the case. Oxalates had been found in the urine.

Mr. **CHARTERS SYMONDS** showed a case of Malignant Goitre after two operations in a woman. The growth was first seen in September, 1897, and affected the left lobe only; it was hard, fixed, and nodular. The thyroid cartilage was pushed over to the right. There was morbid dyspnœa so that tracheotomy was becoming necessary. There was a history of a thyroid swelling for nine years which had been stationary till 18 months before the September of 1897. In October, 1898, a part of the growth was removed and a tracheotomy tube was introduced. The pressure was so much relieved that the tube was removed in six weeks. A second and more extensive operation was performed on April 18th, 1899, as the pressure had again returned. At this operation an attempt was made to remove the whole of the growth. The trachea was exposed and freed from the growth, the upper and central parts being easily extirpated. It was thought unwise to remove the lowest part because of the relation to the great veins. The interest of the case lay in the very little bleeding that occurred; in the relief afforded; in the unilateral character of the growth; and in the long history of a local enlargement before the malignant growth appeared. Mr. Symonds referred to another case which he had treated in a similar way. The growth was a true epithelial formation. At the present time the patient was comfortable, could sleep without stridor and, save for a small tracheal fistula, suffered little inconvenience. There was complete paralysis of the recurrent nerve.—Mr. **ARTHUR BARKER** asked if the other case which Mr. Charters Symonds had seen had run as chronic a course as this one. It seemed to him that malignant disease of the thyroid gland was somewhat peculiar in this respect and he mentioned one case in which the enlargement had existed for six years before it took on what seemed to be a malignant growth and then it lasted for 12 years, during which time six operations had been performed. He had brought the case before the Pathological Society of London and the Morbid Growths Committee had decided that the microscopic appearances were undoubtedly malignant. He had also met with another similar chronic case.—Mr. **CHARTERS SYMONDS**, in reply, said that this case had only had a history of three years. His other case had been less chronic than those referred to by Mr. Barker. It was to be remembered that there were certain adenomatous forms of thyroid tumour which very much resembled malignant disease.

Mr. J. **JACKSON CLARKE** exhibited a case of Ankylosis of the Temporo-maxillary Joint in a girl, aged nine years, who had had complete fixation of the lower jaw for over three years dating from soon after an attack of scarlet fever. When the condition was first noticed the patient was taken to a London hospital, where, after an unsuccessful attempt to break down adhesions, the molar teeth on the left side were removed in order to allow the patient to be fed. Her appetite during the three years had been very large but she remained very thin. At the North-West London Hospital in November last Mr. Clarke exposed the right temporo-maxillary joint by an incision planned to avoid the trunk of the facial nerve, the parotid duct, the superficial temporal artery, and other structures near the joint, and removed the whole of the neck of the bone. The result of the operation was entirely satisfactory. After a few days the patient could masticate food. On leaving the hospital 14 days after the operation, the patient had gained six pounds in weight, although she was now satisfied with a smaller quantity of food. At the present time she could open the mouth more than an inch. Mr. Clarke referred to another case in an adult with bilateral ankylosis where he had performed similar operations on both sides. In this case an equally good result was obtained and up to the present time, nine months after the operation, the patient had improved rather than otherwise, having by exercise obtained a greater power of protruding the jaw.—Mr. **ARTHUR BARKER** remarked that the improvement in these cases was a permanent one. It used to be thought that stiffness due to synostosis occurred even after operation, but that was in pre-antiseptic days, and Mr. Clarke's case reminded them that this synostosis did not occur under modern aseptic methods. He referred to a case of a child who had suppurative mischief in the joint at the age of five years on whom he had operated successfully at the age of 14 years. Mr. Clarke's case was also interesting from the fact that there was not much muscular atrophy on the side of the operation, as there had been in some cases which he had seen.—Mr. **CLARKE**, in reply, referring to the prognosis in these cases, hoped that the facial contour would improve in time, that the bone which now lagged behind would come forward, and that the muscles would fill out.

Mr. **FREDERIC S. EVE** exhibited a case of Arthrectomy of the Knee for tuberculous disease with restoration of movement. The patient was a girl, 13 years of age, who was admitted to the Evelina Hospital with all the usual signs of strumous disease of the knee. For six weeks she was treated with Scott's dressing and strapping, the limb being placed on a splint. No improvement resulting, on June 13th Mr. Eve performed a complete arthrectomy, removing the whole of the thickened synovial membrane. A thin slice was removed from the extremity of the internal condyle where the cartilage was destroyed. The lateral and crucial ligaments were carefully preserved, but the semilunar ligaments were removed. The incisions in the capsule were brought together by silk sutures. A month after the operation the adhesions were broken down under chloroform, and from that time passive movement was kept up on two or three occasions under anæsthetics. The limb was now quite straight and firm, the knee could be flexed to a right angle, and the patient walked firmly and evenly upon it. She wore a splint every night to obviate the tendency which these joints sometimes had after arthrectomy to flexion He thought that after a period of one month was the best time to begin to start passive movement. If less time than this were allowed too much movement resulted and if more, fibrous adhesions might occur —Mr. **ARTHUR BARKER** congratulated Mr. Eve on the success of this case. It realised the desire which surgeons always had in these cases to preserve the movement of the joint. This seemed to be an exceptional success, but he hoped that one day such results would become more frequent. —Mr. **CHARTERS SYMONDS** hoped that the sanguine view expressed about the future of such cases would be realised. He had recently seen a similar case on which he had operated six years before, and the patient, now between 16 and 18 years of age, suffered a great deal of pain in the joint. When these joints had been used for awhile they sometimes gave rise to considerable pain and the permanent benefit was not always realised.—Mr. **J. HUTCHINSON**, jun., had in two cases succeeded in getting a range of 30°, but he had never seen so much range of movement as in Mr. Eve's case.—Mr. **J. JACKSON CLARKE** also thought the result exceptionally successful, for the operation of arthrectomy required considerable selection, and only some cases were suitable. Moreover, the results from the older methods of treatment were not altogether discouraging, and he mentioned some cases in point.—Mr. **FREDERIC EVE**, in reply, said that the case had been distinctly of the subacute variety of tuberculous disease of the joint, one in which fibrous tissue was undoubtedly forming in the synovial membrane.

Mr. **FREDERIC EVE** and Mr. **HUGHES R. DAVIES** showed a case of Resection of the Lower Third of the Radius and Ulna with Myeloid Sarcoma of the Lower End of the Radius. The patient, a woman, aged 21 years, fell and sprained her wrist in June, 1898. In the following September a swelling appeared at the lower end of the right radius; this gradually increased and when seen in February, 1899, there was a typical myeloid sarcoma of the lower end of the bone. On March 4th, 1899, the lower thirds of both radius and ulna were excised by Mr Eve and all the tendons around the wrist were divided, shortened, and sutured. At the end of six weeks she could write her name and could now write well, use her hands for dressing, meals, and for all ordinary purposes. She could also grasp firmly with the fingers any articles such as a glass or a pen and play the piano by the aid of a leather splint.

Dr. **VOELCKER** showed a case of the Hereditary Ataxy of Friedreich in a boy, aged 12 years, who had been under his observation since August, 1896. There was no family history of any nervous disorders. When the patient was five years of age he was said to have had "German measles" and congestion of the lungs, after which he had St. Vitus's dance, which left him helpless. Since then he had had tremors. When he was first seen in 1896 he was a rather undersized boy, and there were irregular tremors of his head, tongue, and upper limbs, the left side being worse than the right side, and he had well-marked Romberg's sign, but no nystagmus The pupils were equal and reacted to light and accommodation. There was no ocular palsy. Sensation to touch and pain was normal. Coördination was very imperfect. The speech was rather thick. Knee-jerk was not obtained. The patient had no trouble with micturition or muscular wasting. In November, 1897, ophthalmoscopical examination showed atrophy of both discs with old retino-choroiditis and some opacities in the vitreous. In January, 1899, his colleague, Mr. Donald Gunn, reported that the changes in the fundi were briefly those of an old syphilitic retino-choroiditis. During 1899 he had an attack of herpes labialis to which he had been liable. In November, 1899, it was noted that on tickling the soles the great toes were extended. For the last three weeks the unsteadiness had increased and his handwriting had become more shaky.—Mr. **J. HUTCHINSON**, jun., asked on what evidence the condition of the fundi oculorum was regarded as syphilitic. He was not satisfied that because there was atrophic retino-choroiditis the lesion was necessarily of syphilitic origin.—Dr. **VOELCKER**, in reply, said that he based his statement as to the syphilitic nature of the eye lesion on the opinion of his colleague, Mr. Donald Gunn.

Dr. **H. BATTY SHAW** exhibited a case of Erythro melalgia which was under the care of Dr. J. Rose Bradford. The patient was a man, 29 years of age, in whom there was obviously poor circulation Both radial pulses were small and he also exhibited coldness and blueness of the nose. He had met with an injury from a cricket-ball on the left wrist six years previously, but had made a good recovery. Three years ago he noticed that the left hand and wrist were becoming red, painful, and swollen. After this the condition had progressively increased with exacerbations from time to time until the present state had been reached, in which the left hand was of a deep purple colour, much swollen and œdematous The lividity, but not the œdema, extended to the elbow-joint He suffered a good deal of pain, which presented the unusual feature of being worse in warm weather It was also worse when the arm was raised or when he exerted himself. The sensation and electrical reaction were quite normal. The patient wished to have the arm amputated on account of the pain in it and its uselessness.

Mr. **ARTHUR BARKER** showed a man in whom he had removed the Tongue, the Floor of the Mouth, and the Symphysis of the Jaw for a Malignant Disease five years ago. The glands had been removed at a subsequent operation. As far as could be seen there was no recurrence anywhere. The patient could not chew on one side, but otherwise he was perfectly well. The case, he thought, was very encouraging.

Mr. BARKER also showed a case of Fractured Patella occurring in a man who had been admitted into the hospital three weeks previously. There was very little sign of injury and the fracture, which was the result of direct violence, might have been overlooked had it not been for the Roentgen rays. The skiagram showed an extensive stellate fracture of the patella.

BRITISH GYNÆCOLOGICAL SOCIETY.

Annual Meeting.—Election of Officers.—President's Valedictory Address.

THE annual meeting of this society was held on Jan. 11th, Dr. MACNAUGHTON JONES, the President, being in the chair.

The TREASURER presented his annual report and received a vote of thanks which was proposed by Mr. STANMORE BISHOP, seconded by Dr. HERBERT SNOW, and carried unanimously.—A vote of thanks to the retiring officers was moved by Dr. HEYWOOD SMITH, seconded by Dr. T. M. DOLAN, and carried unanimously.—The scrutineers reported that the officers and council for 1900 had been elected as follows: Honorary President: Dr. R. Barnes. President: Dr. W. J. Smyly. Vice-Presidents: Mr. W. Armstrong, Dr. Clement Godson, Dr. R. H. Hodgson, Mr. F. Bowreman Jessett, Dr. Skene Keith, Dr. L. Landau, Dr. J. Macpherson Lawrie, Dr. J. J. Macan, Dr. R. Milne Murray, Dr. James Oliver, Dr. A. Pinard, and Dr. R. D. Purefoy. Treasurer: Dr. J. A. Mansell Moullin. Council: Dr. W. Alexander, Dr. W. H Bourke, Professor Murdoch Cameron, Dr. John Campbell, Mr. G. Roe Carter, Dr. John H. Dauber, Dr. T. Eastes, Mr. J. Furneaux Jordan, Dr. George E. Keith, Dr H. Macnaughton-Jones, Dr. T. Morton, Dr. W. H. Newnham, Dr. J. Inglis Parsons, Professor A. W. Mayo Robson, Dr. F. W. Ramsay, Dr. C. H. F. Routh, Dr. F. F. Schacht, Dr. W. Japp Sinclair, Dr. W. Slimon, Dr. Heywood Smith, Dr. R. T. Smith, Mr. J. W. Taylor, and Dr. W. Travers. Editors of the Journal: Dr. J. J. Macan, Dr. Arthur E. Giles, and Dr. H. Macnaughton-Jones, jun. Honorary Secretaries: Dr. Arthur E Giles and Mr. Charles Ryall. Trustees of the property of the society: Dr. G. Granville Bantock, Dr. Fancourt Barnes, and Dr. Clement Godson.

The PRESIDENT then delivered his valedictory address on the Correlation between Sexual Function and Insanity and Crime. He said that he wished to inquire how far the process of menstruation affected a woman by originating morbid impulses in the various groups of her pelvic nerves which find their response in reflected neuroses in other organs and thus influence the coherence and stability of her nervous acts. Or, again, in what directions and to what extent the normal fulfilment of ovulation with menstruation developed for the time being erotic impulses, encouraged the state of neurosis generally, or so lowered the psychical and physical inhibitory control as to lead to a hyper-exaltation of the entire nervous system, with increased susceptibility to slight irritations and a weakened will-control that permitted of distorted mental visions and erratic moral acts, vulgarly called crimes, that the woman was helpless to evade or subdue. To elucidate these points he proceeded to inquire whether there was evidence that menstruation, both normal and abnormal, did so influence the woman, and under what conditions it was most likely to do so; and secondly, how far disease of the sexual organs in women was correlated with symptoms of alienation from slight interferences with their mental equilibrium to more profound disturbances, such as melancholia, dementia, or mania. This in turn led to the consideration how far removal of the diseased organs by operation was salutary or otherwise to the woman and to what extent the operation in itself might on the one hand mitigate or on the other hand increase the mental trouble. After discussing these points from the physiological, clinical, and statistical sides he summed up his conclusions as follows: 1. That the correlation of insanity and disordered sexual function arising out of affections of the generative organs was a factor to be taken into serious consideration in the treatment of the mentally afflicted. 2. That where there was ground for the suspicion that some physical condition of the uterus or adnexa existed which might produce or aggravate the mental affection a careful examination, under an anæsthetic if necessary, should be made. 3. That in the investigation of criminal acts committed by women, either during the menopause or while the menstrual function was either active or suppressed, due weight should be given to the influence exerted by its irregularity or abeyance on the mind of the woman; in doing this her previous history and temperament should be considered. 4. That the special dangers of the climacteric period should be remembered and the symptoms indicative of threatening climacteric mania recollected. The principal of these were moroseness and depression of spirits, attacks of hysteria, occasional hallucinations, delusions with regard to relations, unjust dislikes, unfounded apprehensions of some grave crime committed or injury inflicted on them, and suicidal tendencies. 5. That in operations on the female generative organs there was a greater predisposition to mental disturbance than after other operative procedures. 6 That women who have been previously insane were predisposed to a relapse by the development of disease in their sexual organs, and especially to such recurrence of insanity after operation on these organs. Under all such conditions and in the face of these warnings the greatest supervision and care were required to anticipate the insane impulse and to prevent suicide or crime in the case of women who manifested symptoms that were due to a correlation between disorders of sexual organs and mental instability.

A hearty vote of thanks to the retiring President for his interesting and important address was moved by Dr. C. H. F. ROUTH, seconded by Dr. W. J. SMYLY, supported by Mr. E. STANMORE BISHOP, and carried unanimously.

EDINBURGH OBSTETRICAL SOCIETY.

Albuminuria, Multiple Pregnancy, Papyraceous Fœtus, and Placenta Prævia.—Differentiation of Connective Tissue in the Human Fœtus.—The Early Changes at the Caudal End of the Primitive Gut in Human Embryos.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 10th, Dr. MILNE MURRAY, the President, being in the chair.

Dr. JAMES RITCHIE read a paper on Albuminuria, Multiple Pregnancy, Papyraceous Fœtus, and Placenta Prævia. The patient was aged 32 years and was pregnant for the second time. At five months she was complaining of severe headache, breathlessness on exertion, and debility. There was considerable œdema over the body and the urine, which was scanty, was found to contain a large amount of albumin, but it contained no tube casts or blood. The treatment adopted was rest in bed, free action of the bowels, a teacupful of water or whey every two hours, no other food, and 15 grains of sodium bromide four times a day. In a few days there was marked improvement so that milk and water could be given and later some toast. The progress made was very satisfactory and only a trace of albumin was left. In the seventh month there was slight hæmorrhage followed by sharp flooding on the next day. The os was found to be partially dilated and a firm wedge of placenta extruded. As there was no further hæmorrhage the progress was left to nature. The fœtus, evidently about five and a half months, when born was found to be macerated. The placenta was found to consist of one mass, but there was a firm smaller exsanguine portion. The membrane consisted of two sacs, a larger and a smaller; the latter nearer to the os uteri contained a small flattened fœtus. A succenturiate portion of placenta was expelled next day and later some further shreds. For several weeks before confinement the amount of albumin in the urine was small and yet the nutrition of the fœtus was so impaired that it died. The albuminuria of pregnancy occurs independently of heart or kidney disease. Its occurrence during one pregnancy does not indicate that it will recur during subsequent pregnancies. It is due to some condition peculiar to the pregnancy involved—probably some unusual condition in the relation of the products of conception to the mother. It is associated with the development of an unusual toxic condition of the blood. Although a micro-organism has been described in connexion with eclampsia—a diplococcus—it has not yet been proved to have a causal relation. The cause of the albuminuria of pregnancy is peculiarly prejudicial to the nutrition of the fœtus and the severity of the result is not in proportion to the amount of albumin in the urine. Beyond these facts we are still in ignorance of the pathology of the disease and therefore our treatment cannot yet be founded on a secure basis. The bowels should be cleared out. To favour elimination and to increase action of the kidneys nothing is better than water or whey. There is usually a pulse of high tension in these cases and so digitalis is harmful. For the headache a sinapism to the nape of the neck may be used, and bromides may be given for the sleeplessness. After there is a copious flow of urine milk or milk and water may be given. Rest in bed is helpful by diminishing the amount of food necessary to the waste of exercise. After improvement the diet may be increased by other foods if it is found that the change has no effect in increasing the albumin which may be present in the urine.—Professor A. R. Simpson, Dr Berry Hart, Dr. H. M. Church, Dr. J. W. Ballantyne, Dr. Keppie Paterson, Dr. McVie, and Dr. Milne Murray *discussed the paper.*

Dr. Berry Hart read a paper on the Cause of the Differentiation of Connective Tissue in the Human Fœtus, with special reference to the essential nature of Hydatid Mole. Dr. Hart first discussed the development of connective tissue, especially in the myxomatous stage and went on to the fully developed type. He pointed out that the myxomatous *stage was permanent for the umbilical cord, that* the tissue in the villi fell short of fully developed connective tissue, while that in the rest of the fœtus went on ultimately to the higher form. He believed that the relation of the thyroid to myxœdema in the adult, as well as the structure and the evidence of activity of the thyroid in the fœtus, made it highly probable that Semon's theory was applicable in fœtal life, that, in fact, the thyroid secretion favoured the development of connective tissue from the myxomatous to the higher type. He pointed out that the umbilical cord was not vascularised, that the thyroid secretion did not affect it, and thus it remained of a mucous type. He applied the same reasoning to explain the condition of the connective tissue in the villi and in the vitreous humour. He summed up as follows: 1. There is anatomical and clinical, but not as yet experimental, evidence that the thyroid is functionally active in the human embryo. 2. *It begins to develop in fœtuses of four millimetres*—that is, about the third week. 3. It probably causes the development of connective tissue to pass from the myxomatous to a higher stage. Thus (*a*) the cord without vessels and presumably without thyroidisation remains myxomatous; (*b*) the adult vitreous under the same conditions remains allied to myxœdematous tissue; and (*c*) tissues like the villi are also more or less myxomatous according to their age and length of exposure to vascularisation. 4. *The free covering of the somatopleure is also probably* affected by the thyroid. 5. The hydatid mole may be regarded as acute myxœdema of the chorion. 6. Thyroid extract should be administered after hydatid mole abortion. In the hydatid mole we have a mass of tissue of a myxomatous type with, in almost every case, no fœtus. He believed, therefore, from the evidence which he had brought forward that this view of the myxomatous nature of the chorion was a highly probable one. Dr. Berry Hart's paper was illustrated by numerous microscopical *specimens.*—Dr. Milne Murray, Professor Simpson, and Dr. Ballantyne took part in the discussion on the paper.

Dr. Hart then gave a demonstration on the Early Changes at the Caudal End of the Primitive Gut in Human Embryos and its bearing on a case of persistent end-gut in an infant and an extroversion of the bladder, illustrated by several models and diagrams.

Professor Simpson showed Specimens removed from a patient who had been *sent to the Maternity Hospital from* the country. On admission there was found crepitation in the left groin; the vagina and cervix were severely torn, and the vulva was swollen. There was a narrow brim and as the fœtus was alive it was decided to perform Cæsarean section. This was done and the uterus was amputated above the ligature by Porro's method. The child, which was alive, died soon after evidently from fracture of the frontal bone due to forceps action. The mother died in a few days from general peritonitis.

Dr. J. W. Ballantyne showed an Abdominal Teratoma which had been removed by operation from an infant two months old. It was situated in the lesser cavity of the peritoneum, being attached by numerous adhesions to the surrounding parts. It contained skin, fat, pieces of intestine, &c.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on Dec. 19th, the President, Mr. W. J. Horrocks, jun, being in the chair.—Dr. J. Kerr showed a case of Extensive Wound of the Eyeball extending through the Ciliary Region. There had been sympathetic irritation of the opposite eye but this had subsided, leaving good vision. The injured eye had not been removed but the prolapsed iris was snipped off and the lens washed out immediately after the accident —Dr. F. W. Eurich showed a series of Microscopic Sections illustrating the Commoner Diseases of the Breast.—Dr. T. W. Hime showed a specimen of the Bacillus of Bubonic Plague.—Dr. C. F. M. Althorp showed a patient who had been treated by laparotomy when suffering from Tuberculous Peritonitis. The patient was in good health —Mr. P. E. Miall read a paper on Contagion in Modern Times. (The paper was a continuation of one previously communicated to the society on the ancient ideas of contagion.) In the Middle Ages many diseases were considered to be contagious, but some of them were also traced to other causes. Epidemics, for instance, to poisoned air, which idea did not tend to promote ventilation; to putrefaction from internal causes, what they now sometimes called auto infection; to the influence of stars, planets, eclipses, earthquakes, and volcanoes; and to famine or too great plenty, and to supernatural beings. Sometimes there was a strange mixture of natural and supernatural causes. There was little attempt to define the influence of the various agencies. *Diseases were equally indefinite, but Rhazes in* his description of small-pox and measles had introduced the specific element which ultimately altered the whole aspect of the matter. Leprosy was a prominent example of contagious disease, but it diminished in importance after the epidemic of syphilis at the end of the fifteenth century. No doubt the two had often been confounded. The great plague of 1348, since known as the Black Death, drew much attention to the subject of contagion. Many fevers that we *should now call typhus* and consider to be contagious were then looked upon as caused by chills or other causes. Small-pox was by no means thought to be infectious at all times and places and even plague was doubtful to some authorities. What appeared to them an extreme reluctance to admit contagion was sometimes shown, some preferring to attribute a large mortality to fear alone In this matter there had always been sceptics, their minds continually asking "How?" and "Why?" and not being satisfied with *mere contact as* a cause in the absence of some far-reaching theory to explain the *modus operandi*.—Dr. Basil Hall read a paper on Tuberculous Disease of the Great Trochanter and read reports of three cases.

Liverpool Medical Institution.—At the annual meeting held on Jan. 11th the following list of office-bearers and committees was adopted:—President: Mr. Edgar A. Browne. Vice-Presidents: Dr. A. Bernard, Dr. T. B. Grimsdale, Dr. T. R. Bradshaw, and Mr. W. Thelwall Thomas. Honorary treasurer: Mr. H. Briggs. Honorary general secretary: Dr. J. M. Hunt Honorary secretary to ordinary meetings. Dr. John E. Gemmell. Honorary librarian: Dr. W. Permewan. Council: Dr. W. Alexander, Mr. R. A. Bickersteth, Mr. T. M. Dawson, Dr. A. Burns Gemmel, Dr. J. J. O'Hagan, Dr. A. M. Paterson, Dr. W. Macfie Campbell, Dr. James Armstrong, Mr. Owen Bowen, Mr. Andrew Stewart, Mr. W. T. Clegg, and Dr. J. C. M. Given. Auditors: Dr. A Burns Gemmel and Mr. Charles G. Lee. Pathological and Microscopical Committee: Dr. J. H. Abram, Dr. F. H. Barendt, Mr. R. A. Bickersteth, Dr. R. J. M. Buchanan, Dr. A. W. Campbell, Mr. F. C. Larkin, Dr. C. J. Macalister, Mr. G. P. Newbolt, Mr. Frank T. Paul, and Dr. C. S Sherrington. Journal Committee: The Honorary Secretaries to ordinary meetings and pathological section, Dr. F. H. Barendt, Dr. T. B. Grimsdale, Mr. F. C. Larkin, Mr. Charles G. Lee, Dr. C J. Macalister, Mr. G. P. Newbolt, and Dr. W. Permewan.

Bristol Medico-Chirurgical Society.—The fourth meeting of this society was held in the Medical Library of University College, Bristol, on Jan. 10th, Mr. W. H. Harsant, the President, being in the chair.—Dr. G. Parker showed a specimen of Aneurysm of the Aorta.—Dr. Shingleton Smith, Dr. P. W. Williams, Dr. T. Fisher, chell Clarke, and Mr. J. L. Firth discussed the —Dr. T. Fisher showed the following specimens: (1) e from a case of Idiopathic Intestinal Hæmorrhage; cases of Congenital Dilata ion of the Colon; (3) ion in a Strangulated Portion of Small Intestine; larged Spleen and Cirrhotic Liver; (5) Cirrhosis Liver; and (6) Fibroid Dis se of the Heart due hilis —Dr. Stack and Dr. M hell Clarke discussed ecimens.—The President sho ed a Large Fibroid Uterus recently removed by Abdominal Section.— E. Aust Lawrence read a pape on Cases of Vascular le of the Female Urethra.—Dr. W. C. Swayne, . H. C Newnham, Mr. Ewen Dr. Stack, and the nt spoke on the subject.—D W. C. Swayne read a on Notes of a Case of Syn hysiotomy.—Mr. Paul Dr. Aust Lawrence, and Dr. J G. Swayne made some s on the operation.

RDIFF MEDICAL SOCIETY.—At the monthly g of this society, held on Jan th, Sir John Williams, delivered an address on Som Points connected with duction of Premature Labour. e meeting was a large between 50 and 60 gentlemen rom Cardiff and the bourhood being present. The ldress was of great st and of an extremely pra cal character. The er dealt with various points n ssitating the induc f labour, more particularly albu nuria present before oming on during pregnancy, il rating his remarks erence to various cases that had n under his care.— e of thanks to Sir John William as proposed by Dr. Vachell, seconded by Mr. W. W eigh, and carried acclamation.—In the evening me s of the society riends, numbering 35, dined toge r at the Angel , Dr. P. Rhys Griffiths, President, b in the chair.— the toast of "The Queen," the h h of Sir John ams was proposed by Mr. Ebenezer Da s of Swansea, om Sir John Williams was a pupil in early days.— ohn Williams suitably replied.—Vario other toasts ved and a most enjoyable evening was s .

Reviews and Notices of Books.

ir fur Dermatologie und Syphilis.* Band Hefte 1, 2, nd 3. October, November, and De er, 1899. Vienna: W. Braumuller.

IE original articles in the October num are:—1. iloderma Hæmorrhagicum Adultorum, coloured ological plate, by Dr. Piccardi, working in ni's Poli k in Turin. The hæmorrhage is produced b wander of blood corpuscles through the degenerated el walls by rupture of the capillaries. 2. W. Wechs n con utes an article on the Eruptions produced by pyrin. An interesting article by Felix Pinkus on Skin nges in Lymphatic Leukæmia and Pseudo mia, one photographic and four coloured h ical es, which is to be concluded in a future er. On the Bacteria found in Pemphigus Vegetans, her h the Differential Diagnosis between Diphthe nd udo-diphtheria. 5 A Further Communication he ology of Ecthyma Gangrænosum, by F. Hitchm d rl Kreibich, with clinical and histological plates. is affection known in England as the multiple gang f ldren and the ecthyma térébrante of French . their first communication in 1897 they, as Ehle viously done, found the bacillus pyocyaneus in the l d here they confirm their previous view that it thogenetic organism. Paul Witte's concluding artic the Pathogenesis of Gonorrhœal Epididymytis. Altoge is an exceptionally good number.

Heft 2 (November, 1899) of the same volume treats Endothelioma of the Skin, by E. Spiegler, a valuable co ibution, with two excellent coloured and four uncoloured lates of the interesting tumours which occupy the whole calp like a cap, of which the first recorded case was by ncell in the Transactions of the Royal Medical and Chirurgical Society for 1842, reproduced in Plate XC. of Hutchinson's smaller Atlas, and others in Plates CXIX. and CXX. 2. The conclusion of Pinkus's paper on Leukæmia of the Skin. His conclusions are important and interesting but too long for quotation beyond saying that he admits the close connexion of the lymphodermia perniciosa type of mycosis fungoides with leukæmia cutis, but would separate it from the true mycosis fungoides. 3. Natanson writes on the Structure of Cutaneous Horns *apropos* of one on the Eyebrow. 4. Kreibich in writing on the Histology of Pemphigus of the Skin and Mucous Membranes states that pemphigus arises on previously inflamed skin. The paper is not concluded. 5. Almkvist advocates largin (one of the new silver albumin compounds) for gonorrhœal ophthalmia. 6. Uhma treats of a rapid colouring method for gonococci in fresh unfixed preparations.

In Heft 3 (December, 1899) of the same volume the first article is by Himmel on the good effect of the Roentgen Rays on Lupus and their Action on the Skin and its Appendages with a Histological Plate. Rona records two cases of Epidermolysis Bullosa followed by Atrophy of the Skin and Arrest of Nail Growth. F. Pinkus relates a case of Alopecia Congenita or, as he calls it, Hypotrichosis. Juliusberg describes a case from the Breslau Klinik of a psoriasiform-lichenoid eruption—a condition allied to, if not identical with, the parakeratosis variegata of Unna. Kreibich concludes his long paper on the Histology of the Skin and Mucous Membrane begun in Heft 2. Finally, there is a short article by Orbaek on Lichen Atrophicus (of Hallopeau) and Vitiligo. He relates a case of the former and gives the bibliographical history.

All the numbers have the usual *précis* of current dermatological work and literature and reports of societies and show that in spite of rivals the journal holds its own as the leading German periodical on dermatology and syphilis.

The Western Rajputana States: a Medico-Topographical and General Account of Marwa, Sirohi, Jaisalmir. By Lieutenant-Colonel ARCHIBALD ADAMS, I.M.S., M.D., M.Ch R.U.I., F.R.C.S.Irel., Administrative Medical Officer in Rajputana. With Illustrations. Junior Army and Navy Stores, Limited, York House, Regent-street, London, S.W. 1899.

THIS large and handsome volume of some 450 pages relating to a picturesque and interesting country is copiously illustrated with plates and furnished with many tables. It owes its publication to the fact of its author having been officially directed to write a medico-topographical account of the Western Rajputana States. He has, and very successfully, endeavoured to adapt his official report and increase its interest for general readers by introducing into it a brief history of the rulers of the country and a reference to some of the customs and modes of thought of a people amongst whom, he tells us, he has worked for 18 years. Particular attention, the author states in a brief preface, has been given to the fauna and flora of the country and to the legends and superstitions of the people.

A considerable portion of the volume is taken up with a geographical and topographical account of Marwa, or as it is often called, after its capital, Jodhpore, Sirohi, and Jaisalmir, which together comprise the Western Rajputana States. In order to indicate the care with which Lieutenant-Colonel Adams, I.M.S., has gone about his work we may say hat the plan which he has followed is to give a brief general scription of the country, its physical aspects, products— eral and otherwise—population, religions, agriculture, stries, exports and imports, climate, and medical y. This is, in turn, succeeded by a short history three States respectively, together with a description capitals and principal points of interest and the can spend under these conditions are fewer than those which he needs for sleep, and even then they are often interrupted. The importance of sleep to men whose work requires observation, thought, and memory is paramount. Exceptional intellects there are and have been which can work at a high pitch and almost continually with the briefest intervals for sleep during every 24 hours. Such cases, however, must always remain exceptional, and their example cannot be imitated by the ordinary man with success, nor, indeed, without disaster. A John Hunter may retire to his dissections, his books, and his writing after a long and busy day spent in the active practice and teaching of surgery and after three or four hours' sleep rise fresh and vigorous for another day as full of work. Here and there a man of genius may spend his day doing as much work as two ordinary mortals and fill half the night with enough to occupy two more, but very few are the minds capable of this incessant labour. And in no profession is the labour more exacting than in that of medicine, in which, added to the mere mental exertion, there is so often a sense of responsibility which weighs even more heavily. For all civilised men—at any rate, for all those who live in busy towns—the question of sleep grows with the press and hurry of modern life more and more important. For no class of men is it more so than for practitioners of medicine. And the pathology which new conditions of life is ever creating tends more and more towards conditions where the absence of sleep may play a prominent causative part. We improve our sanitation and our general hygiene, and we abolish the plagues of our forefathers, but we work our nervous systems more in a day than they did in a week, and we fall victims to insomnia and the whole train of nervous disorders in which worry, overwork, and want of sleep occur as etiological factors. Sleep all men must have who use their brains much, and especially all men whose work is associated with extra worries such as are so often inseparable from medical practice.

The hours usually devoted to repose are for medical men inevitably curtailed and interrupted. These hours must be supplemented, then, by others not usually given to rest. Medical men must learn to use their chances, or rather must learn to regard as chances for sleep moments which they do not now look upon in this light. They must avail themselves of the brief opportunities which their mode of life usually affords in plenty. If a man could sleep through the intervals during which he is in a train, for example, or in his carriage from visit to visit he would make up the deficiencies of his short and broken nights. All that is needed is practice. The conditions which men demand for sleep are not truly essential. Convenience directed us to work in the light and sleep in the dark and custom has confirmed her directions, adding to night perfect quiet and bodily comfort. But men can learn to sleep without these easy introductions. Boiler-makers grow used to taking their rest beneath the clang of their comrades' rivet-hammers, and the general practitioner can learn to take his amidst the stream of traffic of a busy town. Sleep is no exception to the faculties that can be acquired by practice; and just as the great general learned to drop asleep on horseback when his waking energies were not required, so, too, the busy medical man must learn to keep his health and vigour by using those brief intervals, which he now regards as inevitably wasted, for snatches of that mental repose which is so often denied him at its expected time.

Annotations.

"Ne quid nimis."

THE INVITATION TO THE INTERNATIONAL CONGRESS ON MEDICAL ETHICS.

THE English circular of invitation to the International Congress of Medical Deontology or Medical Ethics has now been issued and some 2000 copies have been sent, mainly to the secretaries of such medical organisations as deal with economical and ethical questions. The secretaries have been requested to distribute the same among the members of their respective societies. If any society has been omitted the secretary or any other member has only to write at once to THE LANCET office stating how many circulars he desires to receive. But as individual medical men and others who have special reasons for being interested in economical and ethical questions affecting the medical profession and who sympathise with the objects of the congress are also invited to become members of the congress, the honorary secretary of the British Committee will be pleased to send them personally a circular of invitation if they will apply by letter, addressed 423, Strand, London, W.C. The congress, as already announced on several occasions, will meet on Monday, July 23rd, at the Palace of Congresses and of Social Economy now in course of construction on the Exhibition grounds. The subsequent meetings will be held at the Paris École de Médecine. The circular now issued gives the rules of the congress and the list of the subjects for discussion, and anyone desiring to read a paper on any of these questions must submit the manuscript of his paper to the Organising Commission before April 1st. Such papers if written in English should be accompanied with a summary in French and it is absolutely obligatory that all resolutions should be translated into French. Papers and speeches may be either in French, German, English, or Italian; but as among educated classes French is more widely understood than any other language and constitutes at present the best international link we possess, it would be very much to the advantage of English speakers if they brought with them a summary of what they intend to say written in French. This would also greatly facilitate the publication of the report of the proceedings. Further, we would urge that it would be an act of courtesy and would greatly facilitate the organisation of the congress if those who intend becoming members would at once notify the fact and send their subscription to the treasurer, M. P. Masson, 120, Boulevard St Germain, Paris. As already stated, the subscription or entrance fee is 12s. for full members and 8s. for participating members—i e., medical students and the wives or families of the full members. The latter cannot vote or take part in the discussion. The payment of fees can be done at once; for, even if the intending member finds at the last moment that he is unable to be in Paris at the date fixed for the congress, he will in any case have helped to secure the success of this work of organisation. By subscribing he will have given another proof of the support the movement is receiving, and in the course of time he will get the printed reports of the proceedings, which in themselves may be a sufficient compensation for the small outlay he will have made. It has been said that the British Committee of Patronage is not representative of the profession. We would observ that there has been no attempt to make this committe representative of the profession as a whole Such an attemp would be altogether opposed to the spirit and object of the congress For it is not a scientific medical congress The object, on the contrary, has been to form a committee representing the efforts made to organise the profession and able to speak on behalf of that small minority who have especially devoted themselves to the study of its economical interests The medical profession as a whole is not organised and does not pursue studies of this description Therefore, if the British members of the congress were a faithful representation of the entire profession only a minority of the members would understand the object of the congress and be capable of taking practical part in its work Viewed in this light it seems to us that the British Committee comprises precisely the sort of elements required for its purpose Nearly all its members are delegated by active and prosperous organisations engaged in solving economical problems The presence of eminent authorities on medicine or surgery as such is not needed at this congress No scientific papers will be read What is wanted is men who have experience in the vexed questions usually discussed under the heading of the "Battle of the Clubs" or "Hospital Abuse," men who have practical knowledge of the difficulties of grouping medical practitioners together and of forming strong unions capable of fighting in defence of their economical interests Most of the members of the British Committee of Patronage have been actively engaged in such endeavours They have won laurels in the struggle Nor is this the case only with regard to the British section, as is shown by the presence of Dr Vandam and Dr Caylits, the president and secretary respectively of the Brussels Medical Union among the supporters of the movement All who have read our account of the fight these gentlemen organised against the Belgian Mutualists will readily admit that they may have much to teach other workers on the same lines Other countries—and notably France itself—will be represented also by leaders and organisers, men who have fought over every inch of ground in the law courts and in Parliaments against those economic forces that tend to degrade and lower the standard of the medical profession Such men as these should ensure the success of the congress—they have the practical experience which will enable them to indicate what is the right course of action

WHEN ADULTERATION IS GOOD

OUR remarks on the alleged adulteration of golden syrup with maize glucose published in our issue of Oct 14th, 1899 (p 1034), have prompted a specialist on the subject to forward us a recently printed (January, 1900) pamphlet containing, he avers, the whole truth about the question Oddly enough he shows by a number of analyses that adulterated syrup is, when regarded as a food, purer than unadulterated In fact, he says it would be more reasonable to regard golden syrup as the adulterant instead of maize glucose and Mr H W Wiley, a recognised authority on the subject, states that syrups of commerce are glucose adulterated with so called cane syrups—that is, with the drippings and refuse of sugar refineries Golden syrup would seem therefore to need a new definition The term was at one time certainly applied to the by product of loaf sugar manufacture, but loaf sugar exists no longer Before 1860 on the introduction of centrifugal machinery and the change that it caused in the nature of syrup, golden syrup became a generic term like "syrup" but of narrower application and lost any significance it may have had in regard either to composition or method of manufacture From that time golden syrup as known to the trade has been prepared in various ways from various substances This declaration throws an entirely new light on the nature and origin of modern "golden syrup" Still we fancy that the public would rather know that they were buying natural syrup from the cane than a sugar derived from the acid digestion of maize The preparation of maize glucose is, however, conducted with great care and there is no reason for doubting the wholesomeness of the product In regard to future action under the Sale of Food and Drugs Act the old difficulty arising from the want of a definition will be encountered Definitions as to certain foods are, it seems to us, essential in the clauses of the Act before certain cases of adulteration can be satisfactorily established We have pointed this out again and again as a defect in the provisions of the Food and Drugs Act In any case the purchaser has a right to get exactly the article in nature, in substance, and in quality that he demands Substitutes may be even better than the original article, but that does not justify deception Fraud is nothing if not impertinent and a somewhat astounding example of this occurred last week A grocer had purchased a cask of brandy which he *thought* was Hennessy's brandy, so he purchased some labels closely resembling that used by this well known firm and attached them to the bottles A person who asked for a bottle of Hennessy's three star brandy was supplied with a sample of the defendant's bottling The magistrate pointed out that the defendant was liable to be sent to prison with hard labour for four months without the option of a fine, but he decided to fine him £10, with £10 10s costs No steps apparently were taken against the printer who had supplied labels closely resembling those used for a well known article, the vendors of which, however, have an effective remedy in their hands in the provisions of the laws of the land

GUARDIANS OF THE POOR AND THE VACCINATION ACT.

THE minimum fee of 5s or 5s 6d for a vaccination where two or more visits have to be paid and an aseptic operation performed is no better pay than a practitioner gets who visits for 1s per visit and 2s 6d for medicine, yet with all this we find boards of guardians who appraise the services of their public vaccinator at a less fee and pass resolutions to ask the Local Government Board to reduce it The real fact is that the anti vaccinationist never dreamt that the public were intelligent enough to accept vaccination provided that it was offered to them on terms that they could accept It is gratifying, therefore, to find that the new Act of 1898 has been more generally useful than was at first expected But we have a report before us of the last meeting of the Wigan Board of Guardians which unanimously passed the following resolution "That in the opinion of this board the maximum charge fixed by the Local Government Board by the Vaccination Order, 1898 for vaccination is too high and requires revision, and that a copy of the resolution be sent to all unions in England and Wales and also to the Poor law Association with a request that the Executive Council take steps to remedy this defect" That such a resolution should be passed by a public body that has never yet paid or proposed to pay the "maximum" fees to its vaccination officers, so far as we know, is beyond comprehension The statement was made by the mover of the resolution that "the charges, as fixed by the Local Government Board, undoubtedly constituted *an outrage* on the liberality of the community" The italics are ours He further said that in 1893 the charge in Wigan was £30, in 1899 it had risen to £192, an increase of £162 but he failed to state that in 1893 vaccination was in abeyance, owing to the guardians neglecting to order their vaccination officer to prosecute the delinquents and that of those vaccinated in 1899 a great many were children who should have been vaccinated in 1897 and 1898. Furthermore he failed to state that the emolument from this "extra" which goes to the district medical officer, as he happens to be the public vaccinator, was very much below the average. One guardian remarked that "vaccination ought to be at a much less price than they are now paying for it." Probably when a new appointment is made this board will ask medical men to tender at a contract price, and will then be willing to publish the prices of the successful contractor. A borough with a population of over 62,000 is not paying a large sum in disbursing £212 in return for two years' vaccinations.

THE COMMON FORMS OF MENINGITIS.

DR CHARLES L. DANA of New York publishes an interesting and opportune paper on this subject in the *Journal of Nervous and Mental Disease* for December, 1899. Few subjects are more perplexing to a student than the different types of meningitis. The classification, never very simple, has undergone constant changes during the last decade. In one of the earliest and most conscientiously made classifications of meningitis, that by Huguenin (published in Ziemssen's "Cyclopædia" nearly 25 years ago), 14 different forms of cerebral meningitis were described. In Grasset's masterly work published about the same time the forms described were acute, chronic, and tuberculous meningitis. The progress made in the past two decades has been shown on the one hand by a gradual simplification of the classification, and on the other by clinical and pathological studies which have added richly to the store of knowledge and obliged us to add two or three new names to the list. Thus, in the recent treatises of Gowers, Oppenheim, and Mills from 10 to 12 types of meningitis are recognised. The various types of the new and the old added together make a total of about "20 different forms, without using the term 'meningismus,' or including acute cerebral œdema or acute and chronic hydrocephalus." The forms of meningitis as seen in ordinary practice are shown by an analysis of 137 cases collected by Dr. Dana from the records of Bellevue Hospital, New York, during the past 15 years. In 46 cases the records of necropsies were also available. The forms of meningitis in the 137 cases referred to include the following:—Purulent or fibrino purulent lepto-meningitis 52 cases, cerebro spinal meningitis 15 cases, serous meningitis of traumatic, alcoholic, or infectious origin 15 cases, tuberculous meningitis 14 cases, internal pachymeningitis (hæmorrhagic and syphilitic) 12 cases, chronic lepto-meningitis three cases, external pachymeningitis from mastoid disease two cases, and unclassified forms 19 cases. Apart from these there were five cases of spinal meningitis. Leaving out the spinal cases there were, therefore, only five kinds of meningitis recognised in ordinary hospital practice It will be seen that the purulent, tuberculous, cerebro-spinal (epidemic and sporadic), and serous are the principal forms, while pachymeningitis is practically only a chronic syphilitic manifestation. "Acute syphilitic meningitis," says Dana, "is certainly most rare, if it ever exists, at least, using the word *acute* in the same way we apply it to other forms" And again, posterior basic meningitis—a phase which only denotes its topographical distribution—is probably a syphilitic or tuberculous disease or a serous meningitis. These hospital figures in Dana's experience seem to coincide in the main with those of ordinary and general practice. Acute spinal meningitis is a very rare disease. Dana confesses that he has never seen a primary case and can find no record of one. It is well to abandon the distinction between cerebral and spinal meningitis in ordinary clinical work, for if pus is found on the cerebral membranes it is almost invariably present in the spinal canal also. Similarly tubercles are often found in the spinal canal if there is a cerebral tuberculous meningitis. Pachymeningitis is a disorder which has received an extraordinarily rich vocabulary of qualifying terms, and the distinction into external and internal types is an academic one. Extra dural abscess would be the correct term for acute suppurations involving the outer surface of the dura. Intra-nasal, aural, and mastoid inflammations are really the morbid conditions in such cases and they call for surgical treatment. A non-surgical pachymeningitis is mostly an internal pachymeningitis. This form of disease is commonly syphilitic and not infrequently hæmorrhagic. The hæmorrhagic form is associated with disease of the blood and blood-vessels and is found practically only in scorbutic children, in some forms of insanity, and in chronic alcoholism. Leptomeningitis both clinically and pathologically occurs in one of three forms, the epidemic cerebro-spinal, the fibrino-purulent, and the tuberculous The first is well known, and in doubtful cases the employment of lumbar puncture enables us to settle the diagnosis if we find the diplococcus intracellularis or the micrococcus lanceolatus. Most epidemics seem to be associated with the former and a few with the latter organism, but there is no way of distinguishing between the two forms except by culture Purulent or fibrino-purulent meningitis is usually a pyogenic infection due to the streptococcus pyogenes or to the pneumococcus of Fraenkel, but may sometimes be due to almost any other pyogenic organism. Clinically it is not possible to distinguish these from one another and all have a high mortality. While tuberculous meningitis is one of the best known and most readily recognisable, the same cannot be said of serous meningitis. Our knowledge of this affection is far from complete. To this class of brain affections should be added the so-called cases of meningismus described by Quincke (1891) and later by Boenninghaus (1897), of which about 40 have been recorded. Some of these have been traceable to the effects of alcoholism with its resultant cerebral irritation, congestion, and œdema, or been assigned to conditions rising from narcotic poisons, cerebral trauma (traumatic serous meningitis), or cerebral exhaustion and starvation. Acute cerebral œdema, usually following severe blows on the head, is associated with symptoms like those of true meningitis, lasting two or three days and then generally disappearing with rapidity. The acute serous meningitis of alcoholism and allied toxic conditions called "wet brain" closely simulates meningitis and lasts about 10 days. A mild delirium, with a temperature of 101° or 102° F. and some muscular twitchings may be observed. The skin is hyperæsthetic and the irritability of its vascular mechanism is shown by the *tache cérébrale* which can be readily evoked. There is some rigidity of the neck with contraction of the pupils, while the tongue is coated and the bowels are constipated. Eventually the patient dies or turns towards convalescence at the close of the second week. The serous meningitis of Quincke and Boenninghaus is an acute hydrocephalus occurring most often in children or in young adults. Sometimes it runs a short course ending in recovery, and sometimes it is rapidly fatal. A few cases are marked by partial remissions and subsequently by gradually developing hydrocephalus. It affects the sexes in equal proportion and pyrexia is present in about one-third of the number of cases. The cause is some form of infective fever in about half the cases. Traumatism, otitis media, and sepsis are occasional factors and bacteriological tests so far have been negative.

FLOATING HOSPITALS FOR WEST AFRICA.

IN a lecture given at the Livingstone Exhibition, held at St. Martin's Town Hall on Jan. 5th, Miss Mary Kingsley, in urging the claims of the Colonial Nursing Association, said that what was wanted on the West Coast of Africa was a hospital cruiser with a staff of nurses and medical men together with the establishment of branch hospitals in the shore settlements. The amount of good that medical science and nursing could do in a country like that of the West Coast of Africa was great, and some such scheme should be devised both for sympathetic and Imperial reasons. There were certain disadvantages attaching to hospital ships, but even a hospital hulk in Miss Kingsley's view was superior to coast sanatoria. There is much to be said for Miss Kingsley's plea and we trust that the Colonial Nursing Association will not allow the matter to drop.

"CHRONIC RECURRING MEMBRANOUS PHARYNGITIS."

IN the *Journal of the American Medical Association* of Dec. 2nd, 1899, Dr. J. O. McReynolds has described a case of this very rare disease. Sir Morell Mackenzie seems to have previously described it under the name of chronic diphtheria, but in consequence of its pathological and clinical differences from diphtheria, the above designation, as Dr. McReynolds suggests, is the best until a more accurate knowledge of the subject is attained. A girl, aged 19 years, in fair health, was under his observation for 14 months. When uninfluenced by treatment the membrane recurred twice or three times a week, persisting on each occasion for one or two days, and then becoming spontaneously exfoliated, leaving the throat apparently healthy. If forcibly and prematurely removed a raw surface covered by glairy material was left, which easily bled on manipulation. The area affected varied, the soft palate was always covered, and the entire pharynx was sometimes involved. Repeated examinations never revealed the diphtheria bacillus, although several years previously the patient had an attack of genuine diphtheria. Streptococci and staphylococci were found in large numbers, but there was no evidence as to their causal relation. The patient was able to follow her vocation with only slight interruptions and the constitutional symptoms were mild. The daily ingestion of raw onions or the local application of nitrate of silver prevented the formation of the membrane for a period of two weeks. After trying a multitude of remedies the writer was convinced that nothing would produce a permanent cure but that the disease would in time spontaneously subside.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THIS institution enters this month upon its second year, and we understand that the number of subscribers and members has steadily increased, that the practical classes have been filled, and that the consultations have been well attended During the coming three months special clinical lectures are to be given on alternate Wednesdays, at 5 P.M., by the President, Sir William H Broadbent, Bart, Dr. G H. Savage, Professor McCall Anderson, Dr. Patrick Manson, Dr. Saundby, and Mr Jonathan Hutchinson. A museum is in course of erection, the builders having undertaken to finish it by March, and it is hoped that when completed this will be an additional source of attraction and interest to the subscribers and members. A new departure has been made as regards the college journal the *Polyclinic*. The first number of the second volume has just been issued. The journal for the future is to be published monthly instead of quarterly, and will furnish a complete record of the clinical work of the college It is to be edited by Mr Jonathan Hutchinson. The laboratories, class rooms, the Roentgen-ray and dark rooms, have been equipped in the most thorough manner, and the medical superintendent is at all times glad to welcome visitors to the college and to afford them an opportunity of becoming personally acquainted with the advantages and facilities which it offers for post-graduate work. One of the departments of work in which the new Medical Graduates' College and Polyclinic proposes to engage is the investigation of special subjects by the agency of permanent sub committees. We are informed that the Committee on Tuberculosis, of which Dr. Heron has been appointed chairman, will meet for a second time on Wednesday next, Jan. 24th, and will proceed according to arrangement to discuss various questions in connexion with the external manifestations of tuberculosis, more especially those coming under the name of lupus. This meeting will be open to all members of the college. Various questions and statements have been drawn up with a view to elicit facts and opinions as to the clinical history of these maladies and their relation to other forms of tuberculosis. Copies of these questions may be obtained on application to the medical superintendent at 22, Chenies-street. The hour of meeting is a quarter past five. The Committee on Climate and Geographical Pathology has elected Sir William Kynsey as its chairman and Dr. A. P. Hillier as secretary, and holds its first open meeting at 5.15 P.M. on Wednesday, Feb. 7th. The region to which it first gives attention is South Africa. It is desired to collect information respecting the diseases and the climate of different regions and districts. Those possessing information on this subject are requested to communicate with Dr. A. P. Hillier and the gift of books and pamphlets will be thankfully received. The committee is a standing one and will no doubt resume the same subject on future occasions as material may accumulate.

PRECAUTIONS AGAINST THE IMPORTATION OF PLAGUE.

THE Local Government Board for Scotland, in a circular letter dated Jan. 15th, 1900, again calls the attention of local sanitary authorities to the presence of plague in Portugal and the necessity for carrying out "with especial care" the measures in force in these islands for preventing the importation of infection. Their notice is specially directed to a General Order issued by the Commissioners of Customs on Oct. 31st of last year. The object of that Order was "to make certain that in carrying out the regulations of the board the medical officer of health shall receive the greatest possible assistance from officers of Customs," and it is pointed out that, on one occasion at least, such assistance was actually declined by an Inspector of Customs. The mechanism adopted for joint action by the medical officer of health and Customs officials for dealing with arrivals from infected ports is briefly as follows. The officers of Customs look to the medical officer of health to inform them from time to time of any particular ports or countries the vessels arriving from which he would desire to visit. In this connexion it is pointed out in the letter of the Board that "the earliest information which would usually be available to this end is that which would be obtained by a regular examination of the news telegraphed from abroad for the purposes of the daily press" On the other hand, the officers of Customs will, in their turn, give the medical officer of health any information which they may possess respecting the arrival or impending arrival of any ships from the ports or countries in question. The term "medical officer of health," it may be noted, includes any duly qualified medical practitioner appointed or employed by a local authority to act in the execution of the orders relating to plague. Attention is also drawn to the possibility of the infection of plague being carried by some of the lower animals, and especially by "rats, mice, and, by natural sequence, cats," and the necessity for inquiring into the evidences of disease in these animals and taking measures for destroying them if occasion should arise. That rats can and do suffer from plague and are an importar to admit of doubt. The susceptibility of mice appears to be very much less marked, and these animals would seem to be far less active agents in the spread of plague than rats. There is, however, evidence that they can aid in spreading the disease and it is believed that they did so to some extent in Formosa, in Jeddah, in Alexandria, and perhaps elsewhere. Cats, the third group of animals mentioned, appear to be even less susceptible than mice. Scattered examples of what have been believed to be attacks of plague in cats have been published from Poona, Worlee, Jawalapur, and elsewhere in India, and from Hong-Kong, Jeddah, Mongolia, Hoihow, Mauritius, and Oporto; but it is perhaps open to question whether in any instance there has been scientific proof that the animals have in truth suffered from the plague.

YELLOW FEVER IN CUBA.

DR. D. L LAINÉ discusses in the November number of the *Revista de Medicina y Cirugia* (Havana) whether it is possible to stamp out yellow fever. On the whole he is hopeful, but he points out that though the great diminution in the number of cases which has been observed since the American sanitary authorities have isolated the cases in hospitals seems to point to the probability of thorough hygienic measures carried on for some years being crowned with success, the pathogenesis of yellow fever is still so enveloped in mystery and previous periods of diminished virulence have led to such illusory hopes that it will be wise not to count too much on the total suppression of the disease.

ST. GEORGE'S HOSPITAL AND THE PRINCE OF WALES'S HOSPITAL FUND.

Mr. Timothy Holmes and Mr. C. L. Todd, the treasurer and secretary respectively of St. George's Hospital, write in the *Times* of Jan. 9th concerning a matter which they naturally have near at heart—namely, the financial position of the hospital. They refer to the fact that the pecuniary position of the hospital is considered by the authorities of the Prince of Wales's Hospital Fund to be such that the institution is not to be assisted from that Fund. Mr. Holmes and his colleagues point out that this is not the case. There is an increase, it is true, in the dividends accruing from funded property. These dividends from 1873 to 1883 averaged about £4000. In 1898 they had risen to £13,662. But there has been a great falling off in the income from subscriptions and donations. "The average of subscriptions and donations from 1873 to 1883 was over £10,600 and in the next decade over £9200. It is now below £8000. ...... And there can be no doubt that the cause of the limited subscription is the general belief that the hospital has immense realised property and is in no want —a belief which, the Governors fear, the report of the Prince of Wales's Hospital Fund will tend to confirm." The writers of the letter conclude:—

> "It must be far from the mind of the managers of the Fund to injure a hospital of which the reigning Sovereign is always president and of which His Royal Highness the Prince of Wales is a gracious and liberal supporter. Yet there can be no question that individual hospitals lose subscriptions in consequence of their friends preferring to give to the Fund and some of our former subscribers have given this as their reason for ceasing to contribute. To the other hospitals this is more than recouped by the sums allotted from the Fund. But to St. George's which receives nothing the loss is uncompensated. The Governors therefore feel it their duty to do all in their power to urge on the public the need for increased support, and trust that they may have your powerful aid in that effort."

There were not wanting those who on the inception of the Prince of Wales's Hospital Fund feared that it would have a depressing effect upon the Hospital Sunday Fund. These fears have not been realised, but it would seem that, secondarily at any rate, the existence of the Fund has lessened the amount of subscriptions to certain hospitals while doing a splendid work for them. It is never safe to assume that any institution can do without the offerings of the charitable because of the existence of a fund the benefits of which may be available. We therefore support the plea of St George's Hospital for increased subscriptions and at the same time hope that the disbursers of the Prince of Wales's Hospital Fund will appreciate the sound logic of Mr. Holmes and Mr. Todd and at the next distribution will place St. George's Hospital on the same footing as similar institutions.

PRONUNCIATION OF THE WORD "ANGINA."

THE November number of the *St. George's Hospital Gazette* contains a short article by Dr. John W. Ogle to the effect that the second syllable of angina is short (angĭna) and not long as commonly pronounced. Dr. Ogle derived his information in 1879 from the Archbishop of Canterbury (then Bishop of Truro), to whose notice the question had in that year been brought by Professor H. A. J. Munro. The pronunciation of Latin vowels, whether long or short, is usually determined by their position in a line of poetry. Angina occurs twice in hexameter lines, but the early editors of the printed editions having made up their minds that the second syllable was long, altered the reading of the MSS. to suit their preconceived views. In Serenus Samonicus, "De Medicina Præcepta," v. 282, the original reading of the MS. was—

> "Angina tum vero mixtum sale poscit acetum"

One printed edition, however, altered this into—

> "Verum angina sibi mixtum sale poscit acetum,"

and another variant was—

> "Ast angina,' &c.

A line of Lucilius (quoted by Nonius) reads in the MSS.—

> ". ... quos una angina sustulit hora,"

but has been altered by the editors into—

> ".. *angina una quos sustulit hora.*"

HEROIN IN RESPIRATORY AFFECTIONS.

DR HENRY D FULTON,[1] from an experience with this drug extending over five years, is able to give an account of its therapeutic value The diseases treated were simple bronchitis, bronchitis with measles, the bronchitis of influenza, chronic catarrhal bronchitis, phthisis, and pneumonia. In December, 1898, when the epidemic of *la grippe* was at its worst in Pittsburg, Pa., the effects of heroin as a cough-relieving agent were prompt and definite, the degree of comfort afforded to the patient being in marked contrast to that derived from the usual remedies. "In those cases in which the patient is harassed by almost incessant cough, or by severe paroxysms occurring in the night, so greatly interfering with rest ...... and leading to an exhausted condition the following day, its good effects were especially noticeable." In *la grippe* the range of its influence is limited apparently to allaying the cough, as it does not otherwise influence the course or duration of the disease. In phthisis its use is followed by most satisfactory results in securing freedom from cough and therefore promoting rest at night. In one case of phthisis with laryngeal disease and a peculiarly distressing cough the effects were most gratifying. In three other cases of phthisis it proved useful. The administration of the drug was begun early in the afternoon (in the case of laryngeal phthisis) and continued every three hours till nine o'clock in the evening, the dose being $\frac{1}{12}$th of a grain. In a large series of cases of acute and chronic bronchitis it also proved valuable "In the acute bronchitis of children," says the author, "its employment is followed by prompt amelioration of cough and it apparently moderates the severity of the attack In chronic bronchial catarrh it seems to have a positive curative value." In measles when the bronchial irritation is a prominent symptom, nothing else was found so serviceable as heroin in suitable doses (from $\frac{1}{32}$nd to $\frac{1}{18}$th of a grain per dose) to tranquillise the persistent cough A solution of heroin for hypodermic injection, prepared by the addition of a small amount of acetic acid, was found equally as efficacious as morphia and less objectionable in certain cases of spasmodic asthma Maximum doses of heroin produce gastric disturbance similar to that following the administration of morphine, but in a lesser degree, and its desired effects can usually, in Dr Fulton's opinion, be obtained by smaller doses without causing any derangement of the digestive functions

INFLUENZA IN DOVER IMPORTANT ACTION OF THE TOWN COUNCIL

AT a recent meeting of the Managing Committee of the Town Council of Dover the medical officer of health, Dr Robinson, in an interesting report alluded to the prevalence of influenza among the inhabitants He characterised the disease at the present time as a veritable plague demanding some attempt to check its ravages He very properly pointed out, as we tried to do last week, that the chief factor in the distribution of the disease is the infectious person of those who suffer from it On two previous occasions the Town Council of Dover have issued notices warning the public of the infectious nature of the disease The later of the two was a quotation from the pronouncements of the Local Government Board and included the following advice with regard to precautions that should be taken —(1) The sick should be separated from the healthy; (2) the sputa should be received into a vessel containing disinfectants, (3) unnecessary assemblages of persons should be avoided, and (4) buildings and rooms in which people congregate should be well ventilated Dr Robinson advised the closure of the public schools for three weeks and his advice was adopted

PRESERVATIVES IN FOOD A QUESTION OF PROCEDURE

NOW that the subject of preservatives in food is being very definitely investigated by a Government Committee with a view to formulating a precise scheme of legislation it is surely vexatious on the part of vestry authorities to persevere in instituting proceedings based on the assumption that boric acid and other antiseptics are injurious to health How is it possible for a magistrate to express a positive opinion that a certain preservative is injurious to health when admittedly the question is trying the utmost abilities of all leading experts to arrive at a pronouncement on this most important point? We must not be represented as saying that the addition of preservatives to food in an indiscriminate way should be tolerated, but it is our opinion that until knowledge is more exact upon the point of injury to health it is not reasonable to push a case for prosecution on this ground. The question of injury to health is *sub judice*, and until this is decided by the Committee on Food Preservatives now sitting it is premature to raise the issue in court. Yet several cases of the kind have been brought before the London courts under the Sale of Food and Drugs Act lately The procedure can do no good and is likely to defeat the well meant intentions of the prosecuting parties It is desirable, we think, that the vestries should wait until they receive from the Government Committee a pronouncement as to what is and what is not permissible in regard to the use of preservatives in food The Food and Drugs Act only warrants these authorities taking action on the ground that boric acid and other preservatives are injurious to health, and while there remains a doubt as to the fact legal action is unfortunate We may *once more state that the public* analyst is not qualified to speak on the question of injury to health, and the fact of his assuming that rôle on occasions only gives strength to the argument that such appointments should be held by medical men exclusively We trust that some patience will be maintained by those who seem particularly vigilant on this question until the law enables us to view the practice of adding preservatives in a clearer light all round, and especially from the points of view of injury to health No real good can be done by instituting proceedings on the lines which we have indicated On the contrary, time and money are wasted and not a little ridicule is bred

THE ANNUAL (1898) REPORT OF THE MEDICAL OFFICER OF HEALTH OF LONDON THE LONDON MEAT-SUPPLY

THE report of the medical officer of health of the Administrative County of London for 1898 has just been issued by the London County Council It deals with many subjects of the first medical interest, to the consideration of which we shall return in a future issue Meanwhile we briefly indicate some of the more important matters contained in the report Thus we find considered the question of diphtheria in elementary London schools, the influence of antitoxic serum on case mortality in the county, and the occurrence of plague glanders, and anthrax, of which last disease there were five cases admitted into Guy's Hospital, which all recovered after operation In Part II are considered, besides other subjects, those of overcrowding and the seasonal variation in age incidence and fatality of infectious disease In Part III we find discussed the regulation of houses let in lodgings and various subjects connected with food supplies such as unsound food, upon which hangs not loosely the question of the provision of public slaughter houses Only a small amount of meat was seized as unsound in London but this "is no doubt due to the fact that much of the meat which is consumed in London is not inspected at the time of slaughter." The conditions existing in London give ample opportunities for the admission into the metropolis and for its sale, of meat which cannot be sold in other parts of the country With respect to meat killed in London it is obvious that there can be no efficient inspection of meat at the time of slaughter while the killing is conducted in numerous private slaughter houses The report then goes on to refer to the report presented by the Public Health Committee of the Council This report is printed as Appendix II It details the objections raised by those interested in private slaughter houses so far back as 1873 when the subject was under the consideration of a Select Committee of the House of Commons Most of the objections have practically ceased to exist owing to changes in circumstances during the last 25 years After dealing with these objections the report goes on to point out that the crying need for public slaughter-houses rests upon the necessity for a strict system of meat inspection At the present time meat sold in Smithfield is inspected, while meat from the foreign cattle market at Deptford and from private slaughter houses in the Islington Market is not systematically inspected. Exclusive of the private slaughter houses in Deptford and Islington cattle markets, and of the six or eight such places in the city the number of private slaughter houses in London in 1897 was 467. The report suggests that six public slaughter houses be provided—three on the north and three on the south side of the Thames.

to admit of doubt The susceptibility of mice appears to be very much less marked, and these animals would seem to be far less active agents in the spread of plague than rats. There is, however, evidence that they can aid in spreading the disease and it is believed that they did so to some extent in Formosa, in Jeddah, in Alexandria, and perhaps elsewhere. Cats, the third group of animals mentioned, appear to be even less susceptible than mice. Scattered examples of what have been believed to be attacks of plague in cats have been published from Poona, Worlee, Jawalapur, and elsewhere in India, and from Hong-Kong, Jeddah, Mongolia, Hoihow, Mauritius, and Oporto; but it is perhaps open to question whether in any instance there has been scientific proof that the animals have in truth suffered from the plague.

YELLOW FEVER IN CUBA.

DR. D. L LAINE discusses in the November number of the *Revista de Medicina y Cirugia* (Havana) whether it is possible to stamp out yellow fever. On the whole he is hopeful, but he points out that though the great diminution in the number of cases which has been observed since the American sanitary authorities have isolated the cases in hospitals seems to point to the probability of thorough hygienic measures carried on for some years being crowned with success, the pathogenesis of yellow fever is still so enveloped in mystery and previous periods of diminished virulence have led to such illusory hopes that it will be wise not to count too much on the total suppression of the disease.

ST. GEORGE'S HOSPITAL AND THE PRINCE OF WALES'S HOSPITAL FUND.

Mr. Timothy Holmes and Mr. C. L. Todd, the treasurer and secretary respectively of St. George's Hospital, write in the *Times* of Jan. 9th concerning a matter which they naturally have near at heart—namely, the financial position of the hospital. They refer to the fact that the pecuniary position of the hospital is considered by the authorities of the Prince of Wales's Hospital Fund to be such that the institution is not to be assisted from that Fund. Mr. Holmes and his colleagues point out that this is not the case. There is an increase, it is true, in the dividends accruing from funded property. These dividends from 1873 to 1883 averaged about £4000. In 1898 they had risen to £13,662. But there has been a great falling off in the income from subscriptions and donations. "The average of subscriptions and donations from 1873 to 1883 was over £10,600 and in the next decade over £9200. It is now below £8000. ... .. And there can be no doubt that the cause of the limited subscription is the general belief that the hospital has immense realised property and is in no want —a belief which, the Governors fear, the report of the Prince of Wales's Hospital Fund will tend to confirm." The writers of the letter conclude :—

"It must be far from the mind of the managers of the Fund to injure a hospital of which the reigning Sovereign is always president and of which His Royal Highness the Prince of Wales is a gracious and liberal supporter. Yet there can be no question that individual hospitals lose subscriptions in consequence of their friends preferring to give to the Fund and some of our former subscribers have given this as their reason for ceasing to contribute. To the other hospitals this is more than recouped by the sums allotted from the Fund. But to St. George's which receives nothing the loss is uncompensated. The Governors therefore feel it their duty to do all in their power to urge on the public the need for increased support, and trust that they may have your powerful aid in that effort."

There were not wanting those who on the inception of the Prince of Wales's Hospital Fund feared that it would have a depressing effect upon the Hospital Sunday Fund. These fears have not been realised, but it would seem that, secondarily at any rate, the existence of the Fund has lessened the amount of subscriptions to certain hospitals while doing a splendid work for them. It is never safe to assume that any institution can do without the offerings of the charitable because of the existence of a fund the benefits of which may be available. We therefore support the plea of St George's Hospital for increased subscriptions and at the same time hope that the disbursers of the Prince of Wales's Hospital Fund will appreciate the sound logic of Mr. Holmes and Mr. Todd and at the next distribution will place St. George's Hospital on the same footing as similar institutions.

PRONUNCIATION OF THE WORD "ANGINA."

THE November number of the *St. George's Hospital Gazette* contains a short article by Dr. John W. Ogle to the effect that the second syllable of angina is short (angina) and not long as commonly pronounced. Dr. Ogle derived his information in 1879 from the Archbishop of Canterbury (then Bishop of Truro), to whose notice the question had in that year been brought by Professor H. A. J. Munro. The pronunciation of Latin vowels, whether long or short, is usually determined by their position in a line of poetry. Angina occurs twice in hexameter lines, but the early editors of the printed editions having made up their minds that the second syllable was long, altered the reading of the MSS to suit their preconceived views. In Serenus Samonicus, "De Medicina Præcepta," v. 282, the original reading of the MS. was—

> "Angina tum vero mixtum sale poscit acetum"

One printed edition, however, altered this into—

> "Verum angina sibi mixtum sale poscit acetum,"

and another variant was—

> "Ast angina,' &c.

A line of Lucilius (quoted by Nonius) reads in the MSS.—

> ". .. quos una angina sustulit hora,"

but has been altered by the editors into—

> ". . angina una quos sustulit hora"

HEROIN IN RESPIRATORY AFFECTIONS.

DR HENRY D FULTON,[1] from an experience with this drug extending over five years, is able to give an account of its therapeutic value. The diseases treated were simple bronchitis, bronchitis with measles, the bronchitis of influenza, chronic catarrhal bronchitis, phthisis, and pneumonia. In December, 1898, when the epidemic of *la grippe* was at its worst in Pittsburg, Pa., the effects of heroin as a cough-relieving agent were prompt and definite, the degree of comfort afforded to the patient being in marked contrast to that derived from the usual remedies. "In those cases in which the patient is harassed by almost incessant cough, or by severe paroxysms occurring in the night, so greatly interfering with rest ...... and leading to an exhausted condition the following day, its good effects were especially noticeable." In *la grippe* the range of its influence is limited apparently to allaying the cough, as it does not otherwise influence the course or duration of the disease. In phthisis its use is followed by most satisfactory results in securing freedom from cough and therefore promoting rest at night. In one case of phthisis with laryngeal disease and a peculiarly distressing cough the effects were most gratifying. In three other cases of phthisis it proved useful. INFLUENZA IN DOVER IMPORTANT ACTION OF THE TOWN COUNCIL.

AT a recent meeting of the Managing Committee of the Town Council of Dover the medical officer of health, Dr Robinson, in an interesting report alluded to the prevalence of influenza among the inhabitants He characterised the disease at the present time as a veritable plague demanding some attempt to check its ravages He very properly pointed out, as we tried to do last week, that the chief factor in the distribution of the disease is the infectious person of those who suffer from it. On two previous occasions the Town Council of Dover have issued notices warning the public of the infectious nature of the disease The later of the two was a quotation from the pronouncements of the Local Government Board and included the following advice with regard to precautions that should be taken —(1) The sick should be separated from the healthy; (2) the sputa should be received into a vessel containing disinfectants, (3) unnecessary assemblages of persons should be avoided, and (4) buildings and rooms in which people congregate should be well ventilated Dr. Robinson advised the closure of the public schools for three weeks and his advice was adopted

PRESERVATIVES IN FOOD A QUESTION OF PROCEDURE

NOW that the subject of preservatives in food is being very definitely investigated by a Government Committee with a view to formulating a precise scheme of legislation it is surely vexatious on the part of vestry authorities to persevere in instituting proceedings based on the assumption that boric acid and other antiseptics are injurious to health How is it possible for a magistrate to express a positive opinion that a certain preservative is injurious to health when admittedly the question is trying the utmost abilities of all leading experts to arrive at a pronouncement on this most important point? We must not be represented as saying that the addition of preservatives to food in an indiscriminate way should be tolerated, but it is our opinion that until knowledge is more exact upon the point of injury to health it is not reasonable to push a case for prosecution on this ground. The question of injury to health is *sub judice*, and until this is decided by the Committee on Food Preservatives now sitting it is premature to raise the issue in court Yet several cases of the kind have been brought before the London courts under the Sale of Food and Drugs Act lately The procedure can do no good and is likely to defeat the well meant intentions of the prosecuting parties It is desirable, we think, that the vestries should wait until they receive from the Government Committee a pronouncement as to what is and what is not permissible in regard to the use of preservatives in food The Food and Drugs Act only warrants these authorities taking action on the ground that boric acid and other preservatives are injurious to health, and while there remains a doubt as to the fact legal action is unfortunate We may once more state that the public analyst is not qualified to speak on the question of injury to health, and the fact of his assuming that role on occasions only gives strength to the argument that such appointments should be held by medical men exclusively We trust that some patience will be maintained by those who seem particularly vigilant on this question until the law enables us to view the practice of adding preservatives in a clearer light all round, and especially from the points of view of injury to health. No real good can be done by instituting proceedings on the lines which we have indicated On the contrary, time and money are wasted and not a little ridicule is bred

THE ANNUAL (1898) REPORT OF THE MEDICAL OFFICER OF HEALTH OF LONDON THE LONDON MEAT-SUPPLY

THE report of the medical officer of health of the Administrative County of London for 1898 has just been issued by the London County Council It deals with many subjects of the first medical interest, to the consideration of which we shall return in a future issue Meanwhile we briefly indicate some of the more important matters contained in the report Thus we find considered the question of diphtheria in elementary London schools, the influence of antitoxic serum on case mortality in the county, and the occurrence of plague, glanders, and anthrax, of which last disease there were five cases admitted into Guy's Hospital, which all recovered after operation In Part II are considered, besides other subjects, those of overcrowding and the seasonal variation in age incidence and fatality of infectious disease In Part III we find discussed the regulation of houses let in lodgings, and various subjects connected with food supplies, such as unsound food, upon which hangs not loosely the question of the provision of public slaughter houses Only a small amount of meat was seized as unsound in London, but this "is no doubt due to the fact that much of the meat which is consumed in London is not inspected at the time of slaughter." The conditions existing in London give ample opportunities for the admission into the metropolis, and for its sale, of meat which cannot be sold in other parts of the country With respect to meat killed in London it is obvious that there can be no efficient inspection of meat at the time of slaughter while the killing is conducted in numerous private slaughter houses The report then goes on to refer to the report presented by the Public Health Committee of the Council This report is printed as Appendix II It details the objections raised by those interested in private slaughter houses so far back as 1873 when the subject was under the consideration of a Select Committee of the House of Commons Most of the objections have practically ceased to exist owing to changes in circumstances during the last 25 years After dealing with these objections the report goes on to point out that the crying need for public slaughter houses rests upon the necessity for a strict system of meat inspection At the present time meat sold in Smithfield is inspected, while meat from the foreign cattle market at Deptford and from private slaughter houses in the Islington Market is not systematically inspected Exclusive of the private slaughter houses in Deptford and Islington cattle markets, and of the six or eight such places in the city, the number of private slaughter-houses in London in 1897 was 467 The report suggests that six public slaughter houses be provided—three on the north and three on the south side

These should be in railway communication with the principal cattle markets outside of London as well as with the metropolitan markets. A useful map is provided showing approximately the proposed sites for these establishments. Carcasses are to be examined in each slaughter-house by a competent veterinary surgeon, and each carcass is to be marked in some way that would be evidence of the inspection. We have upon previous occasions expressed our desire to see public slaughter-houses provided and their use after the lapse of a certain period of grace made compulsory. Their provision would enable animals to be killed in a roomy and airy place where proper care would be taken in cooling the meat which could be thoroughly inspected; and in addition cruelty would be reduced to a minimum. The public health work of the London County Council has been up to now progressive along such sensible lines that we may feel assured that they will continue to press for the abolition of the private slaughter-house.

THE man Hopwood, an insurance agent, to whose methods we called attention in our columns on more than one occasion some weeks ago, was committed to the sessions by the Birmingham stipendiary last week for attempting to obtain £100 from a medical man of Birmingham by false pretences.

SIR CHARLES BRUCE, the Governor of Mauritius, has telegraphed to the Colonial Office that for the week ending Jan. 11th there were seven fresh cases of bubonic plague, three of which were fatal; total deaths from plague, five.

THE WAR IN SOUTH AFRICA.

AT the moment of writing there is no official news from Sir Redvers Buller, but there are rumours in abundance about him and his forces. Still there is no reason to doubt that the relief expedition is on its way to Ladysmith and it is possible that we may soon hear some reliable news of the initial stages of the combined movement; but it may not be yet, for there is a good deal of marching to be done, and the transport of material, of stores, of reserve ammunition, and ambulance equipment through a difficult and practically uninhabited country is a formidable undertaking. We must meanwhile be content to possess our souls in patience. If Sir Redvers Buller succeeds the whole aspect of affairs will be changed. The responsibility of those charged with the movement is enormous, and they are unquestionably right in concealing their intentions in order to avoid any risk of jeopardising the integrity and fulfilment of their strategical schemes. National interests, after all, come before those of a national press, as we are glad to see all the better and more respectable class of journals in this country fully recognise and appreciate.

As medical journalists we have, of course, nothing whatever to do with politics, and we need scarcely add that we neither hold a brief for any political party nor are we concerned for the vindication of this or any other Government, except in so far as the war concerns everybody interested in the well-being of the country. Still, in fairness and justice to the Leader of the House of Commons, we feel constrained to say that we do not see why he should have been singled out for all the adverse criticism he has encountered, for his speeches were perfectly frank and straightforward. If he were ignorant and failed to foresee the course which events have since taken in South Africa he was notoriously not alone in this respect. We know, at any rate, that the Leader of the Opposition repeatedly stated that he saw no cause for war; that a little while ago most people were averse to taking any steps that might bring war about until all peaceful efforts had been made to avoid it; and that no one had, as a matter of fact, anticipated that it would be thrust upon us by the Boer ultimatum of October last, or that the Boers would invade Natal territory at two days' notice. Moreover, there is no denying that the relief of Ladysmith and Kimberley has been, and still remains, the strategical obstacle to our progress and the cause of the present deadlock, notwithstanding that the fighting at Ladysmith has in another way delayed the Boers in carrying out their design of massing a large force between Ladysmith and the seaboard to the south until it was too late for them to accomplish their purpose. What the country wants to know is—How it was that we have blundered so egregiously as to the strength and preparedness of the enemy? Why, if Ladysmith—however badly situated naturally—was regarded as the Aldershot of the Cape, it was not long ago put into a proper state of defence? And why more artillery and cavalry were not sent out earlier in the campaign instead of its being almost entirely left to British infantry to cope with the Boer forces, all of whom are mounted?

We do not know whether our readers happen to have perused the report of a lecture recently delivered at St. George's Hall, Langham-place, by Captain Holcroft, late of the Transvaal States Artillery, on "The Secret Arming and Secret Service of the Transvaal Republic"; if not it is well worth doing so, for it contains an amount of precise information not to be found elsewhere in the same compass. Captain Holcroft states that the present war follows upon preparations made on a vast scale and extended to such details even as the adoption of the English bugle calls, the reason for which President Kruger said would be found out one day. Now these things, if they were done, were not done in a corner. How is it, then, that they seem to have been officially unknown or ignored? What have successive Governments in this country been about in allowing this enormous growth of military power on the part of the Transvaal Government in the midst of an important part of this empire? The Boer forces in the field at the present time, according to an estimated calculation of the *Cape Times*, amount to 87,000 men, from which, however, their losses during the campaign have to be deducted, and as we have no means of estimating their resources in the way of reinforcements, it is clear that there is yet a good deal to be done on the part of this country. Although the progress of the war has so far been unsatisfactory and disappointing we nevertheless fail to see that the results have been so completely disastrous as some domestic and many foreign critics would have us believe, or that, after all, the Boer forces have as yet achieved any such material successes as will necessarily affect the final issue. That the war was a formidable undertaking which would at once require a much larger British force than many people imagined and that the Boers would probably be successful at the beginning is what we have prognosticated from the first But we shall soon have nearly 200,000 men in South Africa, and with command of the sea and an open seaboard and a comparatively unlimited supply of men and war material the end should, humanly speaking, be practically certain.

With all the adverse criticism which has, rightly or wrongly, been applied to those responsible for the conduct of the war it is most gratifying to be able to point to the way in which the Army Medical Service has played its part under so many difficult and trying circumstances. Sir William MacCormac has inspected the army hospitals at the Cape and in Natal and he speaks in the highest terms of the medical arrangements as leaving nothing to be desired and expresses surprise at the wonderful recoveries and the very small death-rate. In all the details of the necessary movements of sick and wounded no army has ever before been so well provided as is ours now in the field; and this remark might indeed be also extended to the provision made for the army as a whole. In a soldier's letter to a contemporary, wherein the scale and excellence of the supplies were favourably commented upon, it was stated that the exceptional experience of this war had shown the desirability of having a limited supply of wire cutting pliers issued to the troops to cut through the barbed wire surrounding the Boer entrenchments so as to avoid delay from these obstructions whilst under fire. The writer was employed in the Army Telegraph Department and we only allude to the circumstance because it may be taken as evidence of how little had escaped attention.

We think the Director-General exercised a wise discretion in recommending that a staff of eminent civil surgeons should be sent out to the war, for, apart from any consideration of their exceptional skill, *there is no gainsaying* the force of their professional judgment as to the state of the war hospitals, the adequacy of the field medical arrangements, and the skill and care exercised by the medical officers. The public will be quite content to accept their view on such matters. It is to be regretted that there is not a larger number of regularly trained army medical officers available for field service, for nothing, perhaps, makes up for the absence of military training, but there is a large civil element to supplement their services at the general and field hospitals where they are doing excellent work. The Director-General has still a long list of civil surgeons at his disposal, for capital professional men are very keen to be employed. We learn from all sides that the surgical results of the war are exceptionally good. Partly owing to the more favourable nature of the wounds caused by the Mauser rifle bullet, partly to the invariable employment of antiseptic dressings, and the extreme care used to maintain surgical cleanliness, as well as in a large measure to the pure and aseptic atmosphere of the South African climate, the progress of the wounded is all that could be desired. The results of some of the wounds as given in Sir William Mac Cormac's further admirable notes, which we publish to day, are simply amazing.

There is no sign of decreasing enthusiasm in this country or the colonies to render all possible aid, and any number of troops, field hospitals, and medical men are forthcoming. The fact that this is so is a source of extreme satisfaction to all and, it is needless to say, of the highest and most gratifying import to the British Empire. It is hoped that the Yeomanry hospital will be ready for dispatch by the end of the month. Application has been made for upwards of 100 men of the St. John Ambulance Association. The war literature, even so far as it only relates to the contributions and gifts connected with the medical branch of the South African Campaign, has become so voluminous that it is impossible to make such a *précis* of it as shall afford any adequate notion of its extent or of all that is being done for the sick and wounded

The latest sick returns from Ladysmith give 75 cases, mostly of dysentery and enteric fever, among the garrison. This is nearly 1 per cent. of the force. Considering the circumstances and remembering that the siege has now lasted 10 weeks the list cannot be said to be a long one.

In connexion with the war we have received a little book entitled, "Self aid in War, with Practical Hints for the Cavalry Wounded in South Africa," by T. F. S. Caverhill, M B, F R.C.P. Edin, Surgeon-Major, the Lothian and Berwickshire Yeomanry Cavalry (Williams and Norgate, 14, Henrietta-street, Covent-garden, London). This is a little pocket-sized guide in two parts which gives just the hints it professes to give It is well illustrated, the advice given is clear, practical, and judicious, and the information is simple and elementary. The main points to be attended to are printed in more conspicuous type in order to prevent them from being overlooked. It is well worthy of being read by officers and men of the Yeomanry and mounted infantry going out to South Africa and will prove useful as a very portable companion and guide for them in the field The first portion is specially designed for private soldiers and is a translation based on Dr. Diemer's Selbsthulfe The latter portion for regimental bearers is compiled by Surgeon-Major Caverhill from many sources. The price of the manual is 1s.

THE FLYING HOSPITAL.

In THE LANCET of Jan. 13th (p. 129) we mentioned the flying hospital which had been designed by Dr. Horace Manders. Dr. Manders has sent us the following account of the inception and details of the scheme. It will be noted that the modern flying hospital is altogether different from "Napper's Flying Hospital,"[1] which was a hospital train.

"For 16 years (1860 to 1876) the Royal Wilts Yeomanry possessed eight cars carrying riflemen, two to each squadron, with which they manœuvred It was found that they could very well keep up with the mounted men and that ditches and small hedges offered no impediment. In the autumn manœuvres of 1872 these cars were frequently used as escort to the horse artillery attached to the cavalry division of the Northern Army, and wherever the guns went so did the cars. An account of these will be found in the *United Service Magazine* (August, 1890). These cars were originally intended as ambulances for the Crimea, taking the wounded from the front to Balaclava Harbour, but were never sent out as the war came to an end. When serving as a trooper in the regiment and watching the action of the cars during the manœuvres it occurred to me then of what extreme value such cars would be to cavalry if fitted up with splints, dressings, instruments, &c. Now that the nation are sending out a vast number of Imperial Yeomanry the idea that occurred to me years ago has been resuscitated and has taken active shape as the flying hospital, which consists of two cars, one hospital, the other ambulance, the design of which has been placed in the hands of Messrs. W. O. Windover and Co, 22, Long Acre, carriage builders, for execution.

"The hospital car is built after the fashion of an Irish car, but instead of a hollow centre contains a body 6 ft. long by 5 ft. wide, and 1 ft. 9 in. in depth. The footboard on either side falls over the wheel and is made so as to fold over the top of the body. This top opens longitudinally by flaps, flanged so as to keep out rain. Through this opening the well of the interior can be reached, as can also be done by letting down the back of the body. The car can contain four men on either side, with a non commissioned officer on a moveable seat in rear. The well is packed with a regulation operation case, sets of splints, dressings, and utensils, while a cylinder of drinkable water is carried outside along the front. At the sides, on the outside of the body, are carried a lever, two picks, and a shovel, with a bucket slung beneath The car is drawn by two horses attached to a pole, on that modification of the curricle principle adopted in the 'Cape cart,' which allows the greatest lightness, speed, mobility, facility in turning, and the like, combined with the greatest safety. It is almost impossible for this car to be overturned. The horses are driven by a postillion who rides the near horse. The car can live with cavalry and can go wherever horse artillery can go. It occupies but little space and is easily concealed. Its cost is 65 guineas, or, when fitted up with instruments complete, 100 guineas. The contents are: a folding operation table (Jordan Lloyd's), an army regulation operation case, sterilising apparatus for instruments, operation waterproof aprons, Eston tourniquets, Eston instruments, needles, &c, splints (arm, leg, thigh, and finger), dressings, sutures of wood wool, &c., roller and triangular bandages, chloroform and inhaler, subcutaneous injection syringe and tabloids, bottles of antiseptics, cocaine, &c, sponge cloths, compressed food, Maggi, bovril, &c, aluminium bowls, utensils, &c, and a Berkefeldt filter.

"The 'flying ambulance' is built on the same principle as the hospital car, but is slightly longer, being 6 ft. 6 in.; the width is the same. In the well, or body of the car, are two stretchers, side by side, of ashen poles and wire-woven body. The handles of the stretchers at each end fit on and can be securely fastened to the ends of a carriage spring, the centre of which is screwed into the floor of the body. The roof is open but spreads out over the wheels on either side, forming a skeleton platform, on which are screwed carriage springs for stretchers similar to those inside. The platform will accommodate three stretchers, yet give plenty of ventilation to those below, and ventilation is also provided by the louvred sides of the body. A sixth stretcher is carried and can be placed in emergency, transversely across the front, above the water cylinder. Seats are provided at the back for two attendants. The car carries a lever, a pick, and so on, and a few medical comforts An awning is also provided against rain or too great sunlight. The cost of the ambulance car is 65 guineas complete

"The flying hospital and flying ambulance cars are designed to act and work together in harmony. They will follow the fighting line in rear of the supports and in front of the reserves. The moment casualties begin to occur the hospital car is brought up to a sheltered spot as near as can be done with safety from fire, the table is set out, and instruments and dressings are prepared. The bearers unhitch the stretchers from the ambulance and bear them to the front to pick up the wounded and carry them to the place where the cars are standing. This spot becomes at once a collecting station and a dressing station. As the wounds are dressed those wounded in the lower extremities and body are placed in the 'flying ambulance' and taken to the nearest field hospital or bearer company, to the commander of which details are furnished as to the position of the hospital car and probable number of wounded; the ambulance then returns If the horses of the hospital car have not been too much fatigued beforehand the car itself can be used for the transport of those wounded in the upper extremities or head, who are retained in their seats by means of straps arranged for that purpose. The staff required will be: Two surgeons (mounted), one orderly (mounted), one non-commissioned officer (mounted), one non-commissioned officer on the hospital car, eight bearers on the hospital car, two bearers on the ambulance car, and two drivers, one for each car."

---

[1] THE LANCET, Oct. 23th, [illegible], p 1193.

(NOTES FROM SIR WILLIAM MAC CORMAC.)

(Continued from page 123.)

Frere, Dec. 14th, 1899.—This morning the camp here is practically no more. The striking of tents and moving off of the corps began at 1 P M. yesterday and continued until this morning, so that by 6 A.M. nothing remained of the 22,000 men of yesterday but a long snake-like train of bullock waggons conveying commissariat supplies winding as far as the eye could reach along the Chieveley road. We breakfasted at 6 A M., and before 6 30 we had taken the road in our ten-mule waggon *en route* for our hill of observation about three miles along the Chieveley road. The road was blocked with heavy waggons escorted by weary baggage guards, and the dust and heat were terrific. We gradually worked our way along until we managed to get clear of the rest and by a side road succeeded in reaching our hill about 7.30 A.M. We saw with ease the whole army yesterday at Frere, already re-encamped beyond Chieveley, and apparently about two or three miles from the Tugela. The long train of commissariat waggons reached the whole way along from Frere, by a winding road, to the new camping ground, and long after we could see the first waggons entering the new camp the seemingly endless succession was still issuing from Frere. A bearer company flying its Red Cross flags was seen, heading the procession. The reasons for the slow movement of an army in the field were vividly demonstrated to us as we watched this interesting movement. We could see nothing of the Boers across the river, but about 9 A.M. several of our guns opened fire at the range of hills between the river and Ladysmith and we watched the shells bursting far away without any response. Are the Boers in concealment or have they really retired as has been reported? We returned to camp about noon. The place now looks very dreary and deserted and consists of practically nothing but half an infantry battalion as a guard and our No. 4 Stationary Field Hospital on the lines of communication. The hospital train, under Major Brazier-Creagh, R.A.M C., has just moved on to Chieveley awaiting events. No. 4 Stationary Hospital received a warning this evening from the principal medical officer that the hospital must be ready to move at short notice so as to be as near as possible to the battle which was expected to take place on the morning of the 15th.

Dec. 15th.—The booming of big guns and the rapid reports of the quick-firing machine-guns commenced at daybreak. About 5 A.M. a message was received from the principal medical officer to entrain the hospital and proceed to Chieveley, there to await further orders. A fatigue party was at once applied for from the Royal Scots Fusiliers and the work of storing the impedimenta and striking the tents was commenced at once. 24 sick (including two officers) now in hospital were despatched to Pietermaritzburg, so as to leave us ready to receive the sick and wounded in our new quarters to-night, wherever those may be.

Dec. 16th.—We arrived at Chieveley station about 1 30 P.M. yesterday. The cannonading had ceased about 1 o'clock. We found the station occupied by a hospital train under Major Brazier-Creagh, R.A.M.C., and everyone available helping to provide comforts for the freight it carried. There were 119 wounded in the train. They had been taken on board direct from the field, the train having run into the actual scene of action; in fact, it was ordered back by the principal medical officer, two shells having fallen close to it. This train carried the first results of the battle, and it was a very distressing sight. The wounded filled the carriages just as they had come from the field; every wound had been dressed, and had been dressed extremely well, under fire A noticeable feature was the fact that very few of these dressings needed re-adjustment. Rifle splints, tourniquets, and other dressings had been adjusted carefully and deliberately, under circumstances of great difficulty and danger. There had been, we learned, a rush with the wounded to the train, which was rapidly filled and had then immediately steamed away, and when we saw it at Chieveley, four miles from the battle-field, the men were still under the excitement of the action. The wounded were cheerful and thankful for their treatment, many remarking that their chief anxiety was to get back soon enough to pay the Boers out. We saw the train start away for Estcourt (it was back again at Chieveley last night). On its arrival No. 4 Hospital was immediately unloaded and the erection of the tents began at once, before the weary officers and men of the Royal Army Medical Corps had had a chance of sleep. The Stationary Hospital was yesterday, therefore, evacuated of sick at Frere, the whole equipment packed and brought to Chieveley, the tents re erected, made ready for 100 wounded, and almost immediately they received about 50—all this being completed between 7 A.M. and midnight (strength, 4 officers and 37 men of the Royal Army Medical Corps).

To return to ourselves, having obtained the necessary information and permission we walked to the field hospitals of the 4th, 5th, and 6th Brigades, situated about three miles from Chieveley under the crest of a hillock about 400 yards outside the fire zone. The state of these hospitals at the time of our visit (4 30 P.M.) is almost beyond description. Captain Symons and myself visited the three operating tents one after another, where my opinion was continually requested by the medical officers in charge—Major Coggin, Major Heuston, Major Culling, Major Wilkinson, and Major Young—about various cases. Each of the three operating tents contained two operating tables and as fast as a patient was taken off the table another took his place. Awaiting their turn the wounded were lying outside in rows which were being continually augmented by the civilian bearers coming in from the field. As each wounded man reached the hospital he was served with a hot cup of bovril, large cans of which were boiling outside the tents. The way in which the wounded had been dressed upon the field and each man ticketed with the nature of his wound, his name, and regiment was excellent and was very useful for identification. This also saved much time at the field hospitals, because the seriously wounded could be at once discriminated from the more trivial cases. The latter went away at once to the tents and the former were re dressed and operated g we neveren necessary by the four officers of each of the completely itals and the three surgeons of each of the beatics would les. The praise of the regimental officers and have as yet get to the way in which the Royal Army Medicssarily affecl done their duty under heavy fire was unanimoundertakin tinted. An officer of the Devons, wounded, in ish force t told me that he managed to get to a hut near probablyof the river which was being used as a dressing station. This hut was continually under heavy fire, and he described the behaviour of the medical officers as magnificent.

The spectacle at the field hospitals was most painful. Ambulance waggon after waggon and stretcher squad after stretcher squad came in while I was there, pouring in the wounded, some of whom had died on the way and could unfortunately only be carried to the mortuary tents. The work performed in the operating tents was, in my opinion, of great efficiency, the operations being deliberately carried out with skill and dispatch under the very trying circumstances of intense heat, hurry, and excitement all round. The Royal Army Medical Corps officers of these hospitals had started their surgical work about 3 A M, and when I visited them in the evening they were still hard at it, having had no food meanwhile and no time for rest, and the work went on for hours afterwards. I gave advice in many cases where I was asked, and advised against operation in the case of a poor fellow with a fearful shell-wound of the hip. Altogether some 800 patients passed through the field hospitals during the day. The men showed the utmost pluck and endurance; there was not the smallest despondency, the predominant feeling being anxiety to return and fight again. This was very splendid of them after such a day as they had experienced and makes one feel very proud of their fine mettle.

The hospital trains rapidly took them away. Each train carries on an average 100 cases and is equipped with every possible requirement, besides iced soda, champagne, soup, and other comforts in abundance, so I am certain that all that human foresight could accomplish was done during the journeys for the mitigation of the sufferings of the wounded. The first train, which was for a time under fire, left the immediate vicinity of the battle field at 2 P.M. with 119 wounded; a second train was despatched at 8 A M. on the 16th; a third at 2 P M on the 16th, a fourth at daylight on the 17th, and a fifth at 8 A M on the 17th—a very quick succession All the field hospitals were empty at daybreak on the 17th and this was done, notwithstanding that they were obliged to move the hospitals in the midst of their work to escape from the zone of fire

Poor Captain Hughes R A M C (on General Buller's staff, an officer of the highest merit and promise), was killed by a bullet which severed the innominate artery, and Major Brannigan, R A M C, was seen by me shot through the foot Major Stuart Wortley, Rifle Brigade who officered the 2400 volunteer ambulance bearers did splendid service and I heard him report about 5 30 P M that the whole field was then clear of wounded, which was very rapid and good work When I saw that I could do no more personal work for these hospitals we returned to No 4 Stationary Hospital at Chieveley station and managed to get a shake down in the deserted and dismantled house of the station master During the night I assisted Major Mallins to perform a laparotomy on a man whose intestine had been pierced in two places with a very successful issue up to the date of writing (vide recorded cases) It is worthy of note that the operation was performed in a tent (equipped with everything needful) in a hospital which had been in full activity eight miles away on the morning of the same day The conveyance of the wounded by stretchers from the field hospitals and from the field to this hospital has been going on the whole evening, many being carried from five to seven miles with great comfort and at the same time more marquees are being pitched so that 200 beds may be shortly ready All the marquees are provided with iron beds, wire spring bottoms and hair mattresses, the gift of a Durban gentleman Two army nursing sisters (Miss Sammut and Miss Martin) are hard at work doing excellent service under difficulties One of the ambulance waggons which went too far under fire in the morning was blown up by a shell (accidentally, no doubt) Fortunately there were no patients in it and the drivers escaped unhurt

Dec 17th—Yesterday and the day before were indeed days of hard work A hospital train filled with wounded had arrived from the field hospital about 8 A M (16th) and discharged many of the more severely wounded into our stationary hospital A second hospital has now been added to ours under the command of Major Baird, R A M C, assisted by Captain Begbie The two operating tents are constantly busy I was consulted about many cases and assisted at several operations In the afternoon I performed an amputation of the right thigh for a fracture of the femur in which gangrene of the leg had supervened There were many abdominal and lung cases, but comparatively few of these required operation being either of a favourable character or the patient being too ill to allow of interference

An order having been given last evening for the brigades to retire on Frere, No 4 Hospital became of necessity crowded by the wounded of the field hospitals belonging to those brigades By 10 P M all the wounded had been found sleeping places but there were no more beds to spare The medical officers could now do no more till morning than see that the serious cases obtained morphia milk and needful comforts Everyone was exhausted and almost fell asleep at his duties This morning the brigades have left and we hear that the whole army is to retire on Frere Water is very scarce indeed There will probably be no further fighting for the present and as all the wounded will have left the front by midnight to-night the principal medical officer (Colonel Gallwey) has advised me to return to Pietermaritzburg Considering the great strain of the work and the number of the wounded after this hotly contested engagement (where both rifle and shell fire were something, it is said, never seen before) I would like to draw attention to these facts 1 The skill and care displayed in treating compound fractures and injuries requiring calm attention and time under heavy fire 2 The skilful and efficient way in which serious major operations were performed on the same day as the battle (under considerable pressure and disadvantages) by the medical officers of the field hospitals 3 800 wounded were cleared from the field by 6 P M, the action having finished at 2 P M 4 By midnight on the second day after the battle (to-night) the last wounded man will have left the hospitals at the front and will have been conveyed to Estcourt, Pietermaritzburg Durban, and the hospital ships 5 Light train loads have been taken away in the hospital trains in two days There can be no doubt in the minds of those who have watched the proceedings at the front that a trying emergency has been met under circumstances of extreme tension, with complete success, and I know that the army has had the greatest confidence in its medical corps and feels that all has been done for the wounded that could have been done I accordingly returned this morning in the hospital train (conveying 120 wounded) to Pietermaritzburg The heat has been intense We have had three very busy hard-working days and returned weary and sad for such grievous loss and suffering It was indeed a piteous spectacle of suffering and death but one could console oneself somewhat by the reflection that so much had been accomplished to mitigate the distress and the poor sufferers themselves were full of pluck and endurance I append short notes of the more interesting cases which have come under my notice amongst the wounded in the battle of Dec 15th at Chieveley and Colenso These are, however, of necessity extremely brief The pressure and tension under which everyone was working made the taking of any notes almost impracticable

HEAD INJURIES

CASE 1—The wound was over the right mastoid There was no wound of exit Bleeding occurred from the right ear There was paralysis of the right upper extremity The direction taken by the bullet is not known No interference is contemplated at present

CASE 2—The bullet entered near the left parietal eminence The exit wound with comminution and much elevation of bone was through the left frontal eminence Lieutenant Simson R A M C, trephined after consultation with me on account of increasing tendency to coma, twitching and facial paralysis The pulse and respiration were slow Several fragments and a large portion of the elevated fragments were removed thus allowing free drainage There was a considerable amount of clot which was removed There was great improvement of the paralysis an hour after operation

CASE 3—The entrance wound was in the temporo-parietal region There was no wound of exit There was complete aphasia but no other symptoms The treatment was expectant

CASE 4—The bullet entered two and a half inches behind the left mastoid process A probe was passed inwards through the opening of the skull as far as the temporo-sphenoidal lobe where the bullet was supposed to be lodged No symptoms were present The treatment was expectant

CASE 5—The entrance wound was over the right frontal eminence The exit was two inches above and half an inch to the right of the occipital protuberance There was a large depressed fracture in front Hemiplegia was present on the left side The right pupil was widely dilated There was no facial paralysis Some fragments of frontal bone were embedded in the brain and were removed A flap incision was made which connected both openings and a fissured fracture was found between the exit and the entrance wounds through which there was free bleeding from a branch of the middle meningeal artery The skull was trephined and bone was removed close to the anterior opening and bleeding was arrested by plugging The wound was dressed The temperature three days after injury was 100 4° F (in the evening)

WOUNDS OF THE LUNG

CASE 1—I saw with Major Mallins the case of a man with the entrance wound through the upper part of the left deltoid muscle The bullet emerged near the eighth rib on the right side four inches from the spine The bullet must have traversed both lungs and the vertebral column as there was complete paraplegia from the umbilicus downwards I advised, of course, against operation The man presented on his chest and both arms splendid examples of tattooing Poor fellow!

CASE 2—The bullet entered just at the acromion process of the right scapula, it must have traversed both lungs, as it emerged on the left side on a level with and two inches from the last dorsal spinous process He had slight hæmoptysis, but no other symptoms whatever, and is doing quite well

CASE 3—This man was lying down when shot The bullet first passed through his helmet, then entered at the superior internal angle of the left scapula, and emerged opposite the middle of the sixth rib on the same side There was slight hæmoptysis, which has passed off. He feels, he says, quite well and apparently is so.

CASE 4.—The entrance wound was through the middle of the right deltoid. The exit was opposite the tenth dorsal vertebra one inch to the right of the spine. There was much pain and dyspnœa but no hæmoptysis. His general condition was otherwise favourable. The treatment was expectant.

CASE 5.—The entrance wound was through the right infraspinous fossa below the centre of the spine. The exit was on the left side below the last rib in the mid-axillary line. No symptoms of any kind have shown themselves.

CASE 6.—The entrance wound was in the third intercostal space, on the left side, in the anterior axillary line. There was no exit wound. There was some dyspnœa which subsided. is doing well.

CASE 7 —The entrance wound was in the third intercostal ace, three inches from the right margin of the sternum. ne bullet emerged two inches below the inferior angle of ie right scapula. The man ran 500 yards after the injury. here was slight hæmoptysis, but no other symptoms. He s doing quite well.

CASE 8 —The entrance wound was just beneath the right coracoid process, but the bullet was cut out from beneath the skin in the opposite lumbar region, where a large hæmatoma was present He is getting on quite well. No other external injury can be found and it is supposed the hæmatoma and bruising may possibly be the effect of a shell explosion. There were no chest symptoms.

CASE 9.—The entrance wound was beneath the anterior fold of the right axilla. The exit was at a precisely corresponding point on the left side. He had hurried respiration, but the pulse and temperature were normal. There was no hæmoptysis. He is apparently doing well.

CASE 10.—The bullet entered at the tenth rib, four inches from the spine on the right side. The rib was fractured at the point of entrance. There was no exit. There were no symptoms with the exception of a little pain and cough on movement, accompanied by some hæmoptysis.

WOUNDS OF THE ABDOMEN.

CASE 1.—I was sent for last night after my return by Major Kirkpatrick (senior medical officer of No. 4 Stationary Hospital) to see a case of abdominal injury. A bullet had entered on the left side, behind, about two inches vertically above the posterior-superior spine of the ilium. There was no exit wound. The poor fellow had been wounded some hours before and was now lying with a tense abdominal wall and suffering much pain. I advised exploration. There was evident incipient peritonitis, but nothing to indicate in which direction the bullet had travelled. Major Mallins performed the operation and I assisted him. He made a median incision below the umbilicus. After opening the abdomen a slight fæcal odour was perceived. The pelvis was full of fluid blood and on handling the intestine gas bubbled through the blood. After careful search two wounds were found about one and a half inches apart in the ileum. These were closed by Lembert's sutures applied in the long axis of the bowel. No other lesion could be discovered. Saline washing out afterwards and closure of the external wound were performed This morning the condition of the man was favourable. The operation was done in a tent with a very poor candle light and under all the difficulties incidental to the situation. Major Mallins performed the operation with much care and in quite an admirable manner In the first operation in this hospital, I hope the man may recover, but nothing could be seen of the bullet, and it may have caused further injury.

(After doing well for two days collapse set in and death followed.)

CASE 2.—The entrance wound was just below and external to the anterior superior spine of the ilium on the left side. The exit wound was at a corresponding point on the right side. Apparently it was an intestinal injury. The man had peritonitis and his condition precluded any operation. There was no blood in the urine when drawn off.

CASE 3 —The entrance wound was below the ninth right costal cartilage. The exit wound was near the first lumbar spine close to the spinal column on the same side. There were no symptoms.

CASE 4.—The bullet entered opposite the last dorsal vertebra, a short distance from the spine on the left side, and emerged at the anterior superior spine of the ilium on the right side. There were no symptoms.

CASE 5.—The bullet entered one inch from the spine on the right side at the level of the tenth dorsal vertebra. There was no exit wound. He walked about 20 yards to a ditch. Paralysis of the left lower limb followed in the night and great pain down the back of the thigh. The pain was now gone and paralysis only remained in the foot. The treatment was expectant.

CASE 6.—The bullet entered at the margin of the right rectus muscle on a level with the ninth rib. The exit was close to the spine, immediately above the posterior superior spine of the ilium on the right side. Peritonitis had set in and the man's condition was already hopeless. No operative interference was justifiable.

CASE 7.—The entrance wound was one inch above the right posterior-superior spine of the ilium. The exit was in the semilunar line at the level of the umbilicus on the left side. There were no symptoms. The treatment was expectant.

CASE 8.—The bullet entered just to the right of the last dorsal vertebra There was no exit wound. There was paresis of the lower limbs The abdomen was rigid. Peritonitis was present. No operative interference was warranted.

CASE 9 —This was the case of a young officer. The entrance wound was one inch above and one inch to the inner side of the left anterior-superior iliac spine. The exit wound was at the sacro-iliac articulation. There were wounds of the rectum and of the sigmoid flexure, compound fracture of the forearm, and shell injury to the knee, joint probably unopened. He was too ill for operation and died at midnight, Dec 16th–17th.

CASE 10.—The entrance wound was over the eighth rib in the mid-axillary line on the right side. The bullet was cut out at a point one inch to the right of the first lumbar spine. Both wounds have healed. There were cough and slight hæmoptysis. There were very severe hæmaturia and blood in the stools which still exist to a certain extent. The last urine was much clearer. The temperature three days after injury was 101° F (evening). There was also a flesh wound through the supinator muscles of the right forearm, high up. Two days later there was a steady improvement.

WOUNDS OF THE LOWER EXTREMITIES.

CASE 1.—The entrance wound was at the middle of the thigh anteriorly. There was no exit wound. The femur was fractured. Splints were applied.

CASE 2.—This was a large shell-wound of the right hip. A mass of flesh of the size of a cocoanut was gouged out between the tip of the trochanter and iliac crest, which was extensively fractured The anterior portion of the ilium was also comminuted. I found the femur intact, but the upper surface of the hip-joint was laid bare, and the capsule was apparently intact I removed a large piece of the ilium and left another fragment which was attached. The wound was stuffed. The surgeon in charge was contemplating amputation at the hip joint, which I dissuaded him from as it did not appear to me to be indicated I saw this man in the base hospital on Dec. 19th, doing quite well, and the hip joint apparently intact. His temperature was normal.

CASE 3 —A poor fellow received a gunshot wound on the outer side of the middle of the thigh. This caused a comminuted fracture of the femur, and when I saw him to day there was a dark patch of gangrene on the outer side of the leg. There was no exit wound. I advised amputation close to the seat of fracture. The limb was much swollen and infiltrated and the artery was obliterated. At the invitation of Major Mallins I amputated the limb, and on examination the lower third of the femur was found to be very extensively shattered and the femoral artery was torn across just as it passed through the opening in the adductor magnus, probably by a sharp fragment of bone which was found projecting at this spot This was the first amputation performed in the hospital, and I preserve the specimen as a good example of its kind for presentation to the Royal College of Surgeons of England by its President. Two days later the man was doing quite well.

CASE 4 —A man arrived this evening shot through the foot. The bullet had traversed the instep from above downwards and forwards, and was firmly impacted in the sole of his boot. It had just gone through the sole, which was very thick, starting a nail and just showing the nose of the bullet outside, while inside the boot the bullet projected a quarter of an inch above the sole.

bullet entered two and a half inches below the left tibial tubercle on the inner side. The exit wound was at the back of the calf at the same level, passing through the tibia. 24 hours later there was no pain—the man could stand on his limb if he tried and there was certainly no complete fracture. He lay eight hours on the battle-field.

CASE 6.—A bullet entered the middle of the thigh anteriorly and emerged at the upper part of the popliteal space in the median line. A gangrenous patch had formed on the dorsum of the foot and over the external malleolus. The popliteal artery had no doubt been damaged. The patient is in perfectly good condition, with a normal temperature, and says that he feels nothing the matter with him. The general circulation in the limb is re-established. I advised waiting for a clearer definition of the limits of the gangrene. There is just a chance that a Syme's amputation might be performed, but it will be more probably necessary to amputate below the knee-joint.

Those wounds which I saw but a few hours after they were inflicted were all quite small at both the entrance and exit apertures. There was no hæmorrhage and nearly all had become sealed up spontaneously. The rapid manner in which they heal, or close up, rather, under a scab, is quite extraordinary. I have not seen any suppuration and external hæmorrhage is quite exceptional. What causes me never-ending surprise is the number of wounds traversing the lung, and in many instances both lungs, without causing greater inconvenience than temporary and insignificant hæmoptysis, and often not even that. Another feature is the number of abdominal wounds in which no serious consequences have taken place, wounds in which from the direction taken by the ball (which may be assumed to be a straight course from the entrance wound to the exit wound) it is impossible to conceive that the visceral contents have escaped perforation, and in which, nevertheless, no serious consequences arise. It may be that the opening in the intestine is so small that it closes up, as the external wounds certainly do, without allowing extravasation to occur. In three instances in which I saw wounds of the intestine of this sort after laparotomy it appeared to be quite conceivable that this could actually happen and that it does happen. Either mortal damage is inflicted, in very many instances, when no operation is feasible, or the injury is recovered from without inconvenience to the sufferer. The most extraordinary head wounds with damage to the brain seem also in many instances to entail no mortal results.

Pietermaritzburg, Dec. 20th, 1899.—The notes of the cases ollowing were taken at Pietermaritzburg on Dec. 20th. They re of cases wounded at the battle of Colenso on Dec. 15th.

HEAD INJURIES.

CASE 1.—The entrance wound was in the middle line of e nape of the neck, opposite the third cervical spine. The xit wound was on the left cheek, one inch external to the a of the nose and on the same level. The superior maxilla as fractured and the upper molar teeth on that side were slodged.

Second wound in the same case.—The entrance wound was o inches above and 1¼ inches behind the tip of the left ochanter major. The exit was one inch below the fold of e right buttock and one inch behind the femur. There re no symptoms.

CASE 2.—The entrance wound was in the right coronal ure, one and a half inches from the median line. e bullet passed through the left side of the palate opposite second molar tooth and was cut out of the neck on a el with the hyoid bone in a line with the angle of the r. The wounds healed. No symptoms were present and ound the man walking about against orders. The sight he right eye is impaired, definition is absent but vision is lost. He said that he felt perfectly well and did not see y he should be kept in bed.

ASE 3.—The entrance wound was one inch in front of the t parietal eminence. The exit wound was at the erior curved line of the occipital bone on the right side and a half inches from the middle line. There were ptoms of cerebral irritation present. The skull was ined at the entrance wound and small pieces of bone picked out and some brain substance was removed. hing was done at the exit wound. The symptoms were ved by the operation. The pulse was slow (50 per te). There was no headache. He also had walked against orders, saying that he felt so well and had so little the matter with him. The grasp of the left hand was not so strong as the right.

CASE 4.—The bullet entered through the right side of the lower lip about three-quarters of an inch from the free border and became lodged in the lower jaw at the situation of the second premolar tooth on the same side. The bullet is still there and a radiograph taken indicates the situation. There is nothing of special interest about this, for all cases of bullets lodged in doubtful situations are radiographed.

CASE 5.—The bullet entered opposite the midpoint of the sagittal suture and one inch to the right of the median line. The exit was apparently through the lambdoidal suture two inches to the right of the median line and two inches above the superior curved line. There was some vomiting at first, but this soon disappeared. The bullet was found on examination to be tightly wedged in the exit wound, having only in part emerged from the skull, the point projecting through the skull. It was removed with some small portions of bone. The entrance wound was left alone. Five days after injury the temperature was normal; both wounds had healed, and the patient was doing well.

CASE 6.—The entrance wound was a little internal, and one inch anterior, to the left parietal eminence. Another wound, probably the exit wound, was one and a half inches above the left zygoma and half an inch anterior to the pinna of the ear. It may be a second wound but probably is not; there is no other. Five days after injury the pupils were very dilated, but equal; there was facial paralysis on the right side; the right arm was paralysed, but the paralysis was diminishing; the right leg was also slightly paralysed, but was now recovered. No operation has been performed up to date, as the patient seemed to be improving. The pulse was 54. He cannot speak properly, but his intelligence appears to be normal. His general condition is not quite satisfactory, however.

CASE 7.—The entrance wound was one inch anterior to the right parietal eminence and one inch nearer the middle line. The exit was slightly to the left and just above the occipital protuberance. On admission the patient was drowsy. His pulse was 56. There were occasional attempts at getting out of bed. There was no paralysis, but he was very irritable. An incision was made four days after the battle over the entrance wound. A depressed fracture was found about one inch in length with fissuring extending towards the exit wound. He was trephined at the entrance wound. One day after operation he could speak; his pulse is now about 70 and there is no paralysis.

CASE 8.—Before admission to the hospital at Pietermaritzburg this patient had already been trephined. The left pulse could hardly be felt but the right one was very strong. A piece of bone had been removed over the left parietal eminence where the entrance wound was situated. The exit wound was situated at the junction of the parietal and occipital bones near the apex of the lambdoid sutures and a little to the left. There was paralysis of the right arm. The pupils were dilated but equal. He is now perfectly intelligent (five days after the injury) but can remember nothing before the operation. There is no facial paralysis, but he cannot whistle quite distinctly. There is no leg paralysis.

WOUNDS OF THE ABDOMEN.

CASE 1.—The entrance wound was two and a half inches to the left of the spine of the eleventh dorsal vertebra. The exit wound was just to the left of the middle line of the abdomen and three and a half inches below the ensiform cartilage. The wounds healed. There were no symptoms.

CASE 2.—The bullet entered the left buttock at the level of the great trochanter and two inches behind it. The exit wound was two inches vertically above the tip of the right trochanter. Blood was passed in the urine for three or four days, but this has entirely ceased. There is no blood in the stools and no other symptoms. The patient is doing qui well.

CASE 3.—The entrance wound was at the posterio superior spine of the right ilium. The exit was throug the eighth intercostal space in the posterior axillary lin on the same side. There were no symptoms. The wound closed. The patient is convalescent.

CASE 4.—The entrance wound was two [illegible]
half an inch internal to the right nip [illegible] ve and
was just to the right of the median [illegible] d
inches below the ensiform
there

Second wound.—A bullet passed through the right instep from above, downwards, and inwards. These wounds are also closed.

CASE 5.—This patient presented three wounds. The first was about two inches above the lower angle of the left scapula and half an inch external to it. The second was at the lower fold of the right buttock three and a half inches from the anus. The third was half an inch anterior to the anus in the middle line of the perineum. He complained of soreness down the left side of the body and dyspnœa. Constipation was present but this has been remedied by enemata There is no blood in the stools. There is pain on micturition, but no blood in the urine. The wounds have healed with the exception of the perineal one, up which a probe can be passed for one and a quarter inches. There is no hæmoptysis. Abdominal pain is doubtful; there is no tenderness. No urgent symptoms are present. The man seems to be recovering. No bullet has been localised.

CASE 6—The bullet entered one inch above and one and a half inches to the right of the umbilicus. There was no exit wound. The patient complained of slight pain running round the right side but there were no other symptoms whatever. The wound healed. The patient feels well. He will be radiographed to search for the bullet.

CASE 7.—In this patient there was a jagged wound over the left fifth rib in the anterior axillary line. He stated that half his brace buckle was carried away. There was no exit wound. There was at first hæmoptysis, but this has disappeared. There are at present dyspnœa and cough, and much pain on coughing. He suffers great pain at night and requires morphia. He will be radiographed. The wound is probably not penetrating.

WILLIAM MACCORMAC.

(FROM OUR WAR CORRESPONDENT.)

I have already drawn attention to the large number of wounded soldiers sent down to Wynberg, completely filling No. 1 and No. 2 General Hospitals, say to the extent of 1200 or more cases, taxing the resources of the establishments to their uttermost. Hence it became necessary to increase the number of general hospitals in the district. A third one has been brought into requisition. No. 3 General Hospital has been established at a very pretty place called Rondebosch, some three or four miles nearer to Cape Town. The camp, composed of tents, has been pitched on a grassy piece of land to the right of the Diocesan College, and has been laid out and equipped in a most satisfactory as well as expeditious manner. It should provide cot accommodation for another 500 cases. Lieutenant-Colonel Wood is principal medical officer and Major Keogh acts as secretary and registrar. After quitting the train at Rondebosch station by the Sandown road a walk of about 15 minutes brings one to the camping ground, on which are noticed the white tents to the right hand. The lines of hospital marquees cover a considerable extent of ground, which *locale* has been admirably chosen for the purpose owing to the comparatively level surface of the ground. At the bottom of this open space there runs a broad hard road, while a similar vehicular way is preserved in front of the hospital separating the tent of the officers and staff from the marquees below them. Large consignments of stores are observed lying about in various directions all covered with tarpaulins. These will soon be stowed away in appropriate quarters as soon as the tents or huts are ready to receive them. One of the canvas erections has been selected for dispensary purposes and within its walls may be observed any amount of medicines, drugs, disinfectants, surgical appliances, and antiseptic requisites. The quartermaster's store merits a share of attention, for within it are innumerable cases containing goods, as well as luxuries, the gifts of Lady Buller, who seems to have put her sympathy into practice by contributing a considerable share of the comforts to be found in No. 3 General Hospital. When one observes in an adjoining store the quantity of linen, hardware, crockery, &c., which is piled tier upon tier, it becomes plain to the most obtuse that little has been forgotten in equipment, and No. 3 may be well bracketed, as far as excellence of arrangement is concerned, with the two Wynberg hospitals.

At one quarter of the canvas town are two fairly-sized marquees set aside for the use of the nursing sisters, who entered upon their duties about the middle of the present month. I am given to understand that their staff is quite inadequate and incomplete, owing to six of their number having been sent round to the Natal side. No doubt these will return to Rondebosch when the wounded cases come down and their services are required. Behind the stores is located the operating-room, a canvas erection of course; as it is somewhat small for the purposes intended it will possibly be superseded before long by a larger and more substantially built structure. Instruments, operating table, and every other requisite appertaining to a minor theatre being fully in evidence conclusively prove how thorough have been the exertions of those who have had the fitting out in hand.

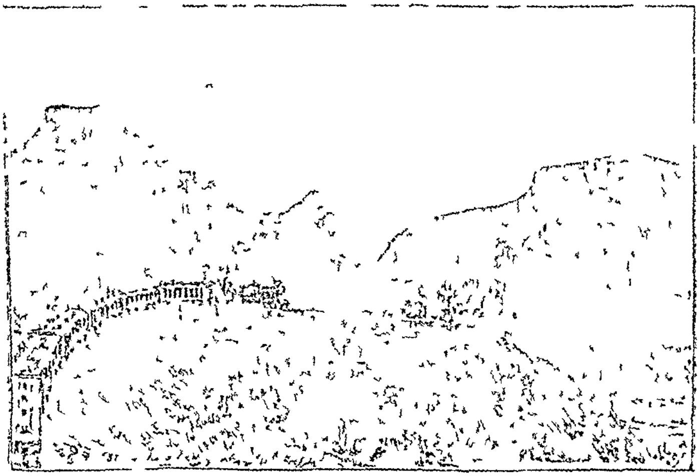
At any period in any campaign infectious diseases, more or less acute, must be looked for and have to be provided against. Hence the necessity of erecting an infectious ward which has been located away and apart from the other tents. The hospital marquees contain the usual number of cots. They are well ventilated and provided with tables, mess receptacles, and other conveniences necessary to a sick room. The ground is covered with tarpaulin, which can be easily cleaned or even removed at will. The soil on which the hospital tents are erected is a light sandy loam. Here great difficulty has been experienced in getting the tent pegs to hold, and no doubt, as at No. 2 Hospital, long iron pegs will have to be substituted for the shorter wooden ones.

Nothing gives a poor sufferer more comfort than a cheerful look-out. He has it at Rondebosch, at any rate, for a more charming and picturesque view could scarcely be imagined. The wounded can lie in their verandah chairs and look upon Table Mountain with its flattened top and enjoy one of the loveliest bits of mountain scenery it is possible to imagine. The temperature during the day is high, the thermometer registering as much as 86° F. in the shade; but there is no moisture to render it oppressive or unhealthy, and as the heat declines with the sinking of the sun the evenings and nights are delightfully pleasant and cool.

A trip to the front must now be referred to. Having duly received my permission to accompany the hospital train I proceeded to the old military hospital at Woodstock, one and a half miles from Cape Town railway station. This was originally intended for the reception of some 80 or 90 patients, but in consequence of the increased demand made by cases arriving from the shipping in the bay and medical cases coming from other quarters, the accommodation has been so much enlarged that upwards of 300 cases are at present treated within its walls. Colonel Supple, R.A.M.C., received me most kindly. To him and his assistants, as well as to Professor Stevenson and Major Conner, R.A.M.C., the hospital train owes the very efficient and highly successful manner in which it has so far been worked. There has been no delay, no breakdown, and everything up to the present has run smoothly, proving that in this special department at any rate the right men have been selected for the right places.

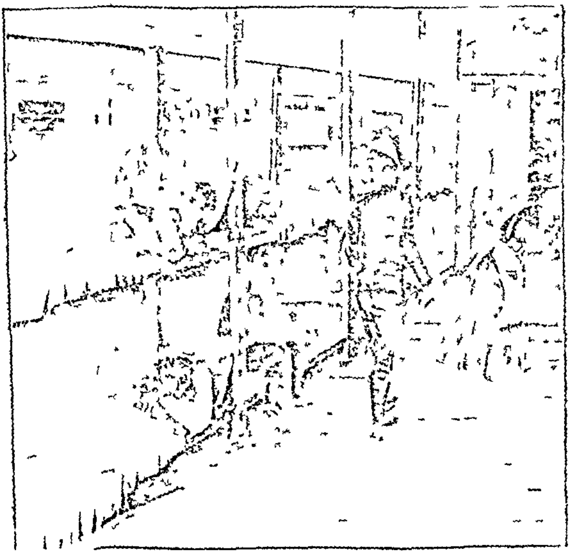
Our train was timed to leave Woodstock about six and within a few minutes of that hour we had quitted. On board the train were the following:—Major Russell, R.A.M.C., in charge; Civil Surgeon Gilbert, second in command; myself, Sister Rose Innes and Sister De Montmorency, two civil cooks, an engine driver and staff, together with several orderlies, men of the Royal Army Medical Corps; the conductor or guard being a Mr. Southgate, an employé of the Cape Town railway staff. Evening was fast closing in by the time we reached D'Urban Road Junction, so that there was little opportunity of noticing the character of the surrounding country through which we travelled, but an appreciable ascent was noticed. Between 9 and 10 P.M. we reached Wellington and took aboard a fresh supply of water. Our arrival had evidently been anticipated, for several ladies and gentlemen were on the platform laden with fruit, flowers, and eggs which were handed to the Sisters for consumption by the sick and others on the train. Such spontaneous and profuse liberality on the part of the inhabitants needs only to be chronicled to be the more highly appreciated by friends and relatives in the mother country. As we ascended the course of the Hex river and were nearing the table land of De Doorns, some 1566 feet (see Fig. 1) above sea-level, the scenery was exquisite, a clear bright moon illuminating the flat-top ridges and intervening valleys for miles around. At this altitude the air was quite

FIG. 1



Stony character of ground traversed by hospital train while bringing down wounded to Wynberg

FIG. 2



chilly, so much so that at midnight I was glad enough to turn in. Although the lines of rails are laid on a stony bed the oscillation was not by any means excessive, the vibration being reduced to a minimum by the use of first-class waggons and a combination system of springs.

The next morning proved to be a regular scorcher. An unclouded sky with an intensely bright sun, and not a breath of air to ruffle the delicate leaves of the mimosa trees which grow in profusion by the wayside, prepared us for a regular "brickfielder" which as the day wore on gradually made itself painfully felt. The hot air blew in scorching blasts upon our faces and hands, and it was with no inconsiderable pleasure that we saw dark, thunder-looking clouds gather on all sides, threatening rain, and the inrush of a cooler column of air. But in spite of the gathering gloom not a drop of rain fell, nor did any sensible reduction of the oppressive temperature take place. De Aar Junction was reached about 6 30 P.M., where there is a large camp. The Queensland contingent, which has been encamped here some days, moved northward this afternoon. From an officer I learnt that all the men were very fit and anxious to get into touch with the enemy. De Aar is 4180 feet above sea-level; but the water is said to be somewhat indifferent, and to its use some minor enteric local ailments are (very probably incorrectly) attributed. About midnight our train was once more *en route* for the Orange River, which station was reached about 6 A.M. the following morning. We had now reached a spot within measurable distance of our foe, for at 12 miles off the place where these notes were jotted down our patrol was fired on by the Boer scouts and one or two English officers and some men were shot. A very large force, therefore, is concentrated at this township. All water is drawn from the Orange river which runs as a light-coloured muddy stream to the northward of the railway station. The fluid is fairly good, and although discoloured by earthy matter is quite fit after boiling for drinking purposes. The train on the passage up did the journey at the rate of about 26 or 27 miles an hour, including all stoppages. At all the stations up and down presents of milk, flowers, eggs, and fruit were made by kindly-disposed sympathisers.

The general daily routine observed on board the hospital train (Fig. 2) was as follows: Rise at 5 30 A M; at 6, clean wards and utensils; at 7, breakfast; at 8, clean and scrub wards; at 11, parade in both wards, after which the medical officer inspected all parts of the train, the various orderlies being at their respective posts, after which patients' wounds were dressed and attended to. We took down 96 wounded in the train. At 1 P M, nner; at 3 the wards were again cleaned up; at 4 ie medical officer in charge again inspected all ompartments, at 5, tea. Three orderlies attended in ach ward, being two hours on and four hours off duty. During loading and unloading of wounded each attendant is told off to a definite post. There is a civilian cook and assistant cook supplied to every train No stimulants as a ration are supplied. An extra allowance ranging from 4*d* to 8*d* daily in addition to the usual pay is sanctioned to every attendant.

Visiting the Orange River Camp on Sunday I learnt that on the day when we felt the heat so oppressive on our way up the thermometer in single-fly tents there had registered the temperature as *115° F. in the shade*, whilst in the double-fly tents it stood only some nine degrees lower. — Of the 96 cases received from the Orange River Camp the greater part were of a very serious character, principally gunshot wounds. There was one serious case of dysentery which terminated fatally a day or two after arrival at Wynberg.

Mr. Makins was a passenger with us on our return trip from the front to Cape Town. He has performed two operations for perforated colon successfully, but all the cases of perforated smaller intestine have succumbed after the operations were concluded

All the advanced field hospitals have been cleared of their wounded and sick Should an advance in force be decided on a clean slate must be exhibited by the principal medical officer accompanying that advance. Nothing would hamper any general more than having to carry his wounded and sick about with him. Casualties are expected and must be, of course, provided for, and already provision has been made both in the hospitals at the base and at the front for the reception of some 3000 more wounded and sick should the resources of these hospitals be unfortunately called into requisition. I enclose a sketch of the interior of the hospital trai [illegible] arranged, also another of the train rounding [illegible] when descending the Hex mountain.

I have to thank Major Russell, Civil Surgeon Gilbert, and Sister Rose Innes and Sister De Montmorency for especial courtesy and attention all the way up and down my long trip of 1200 miles.

Wynberg, Dec. 25th, 1899.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

I mentioned in my letter of last week that the course taken by some of the bullets was little less than marvellous and I think the following case will bear out what I said. A man was shot at the Modder river engagement. The bullet entered a little above and to the right of the occipital protuberance, causing a "gutter fracture", and driving finely comminuted fragments of the inner table into the dura mater and occipital lobe, lacerating and contusing the cerebellum much; it then passed through the deep muscles of the neck and the space enclosed by the first rib, chipped fragments from the second and third dorsal vertebræ, driving them into the lung; then it grooved the eighth and ninth ribs, smashed the tenth and eleventh ribs, found an exi under the twelfth rib, passed through the deep muscles, an was discovered resting on the crest of the ilium. Th man lived for some days after coming to the hospit and he bore the journey down here well. Anoth interesting case was one in which the bullet entered a li above the posterior angle of the right scapula and emer through the left malar bone. The patient was little worse for his injury and the case opens up an interes problem for the anatomist as to what important struc escaped injury in its course. The man was in a [illegible] position when he was shot.

The last batch of wounded from Colenso is composed of not very serious cases and the patients are progressing favourably Several cases of sunstroke have been coming down from the front, and all are agreed that the felt wideawake used by several of the colonial corps is not an adequate protection from the sun during this season of the year, and the sooner the Wolseley or Indian helmet is made *de rigeur* the better. The wounded officers in hospital number to day 64, exclusive of convalescents sent to the sanatorium at Claremont. Up to date they are all progressing favourably and we have been able to send several back to the front. A large consignment of wounded officers and men have left for England in the *Pavonia*, mostly cases that will require extended treatment at Netley.

The instances where large arteries have been wounded and traumatic and diffuse aneurysms have resulted have been on the increase. During the past week several have been operated upon and it still remains a moot question whether ligature of the artery above the aneurysm or cutting down directly on it and turning out the clots and securing the bleeding points gives the best result; both procedures have been tried and I am inclined to favour the latter when possible. Fractures of the femur from bullet-wounds still occupy a great deal of our attention and their progress as a rule is very slow, but I am glad to say that the results as a whole are good and that the amount of shortening has been slight. One or two of these cases in which the patients had remained for some time on the field before being brought in have been received in a septic state and have done badly. Very few abdominal cases have been sent down, but those that have are on the high road to convalescence, in particular one in which the bladder was also wounded, in which the patient has done well and has been sent to Netley. There is again a lull in the proceedings, no fighting except a few skirmishes having taken place since the Colenso battle. No. 4 General Hospital is to be established at De Aar and is to leave Cape Town in a few days.

Everyone was much distressed at the news of the death of poor Hughes, R A M.O., and his loss will be especially felt by General Buller on whose staff he was. It was only a few weeks ago that he was going round the wards here and taking the greatest interest in the various cases. I am glad to say that Lieutenant Douglas, R.A.M C., who was wounded at Magersfontein is nearly well. He had a very narrow escape I hear that he has been specially mentioned for his bravery under fire

I cannot help thinking that in future campaigns where the modern arms of precision are used it will be necessary to augment considerably the capacity of the present general hospitals both for officers and men The fact that accommodation in a general hospital as regards officers is limited to 25 cases points *to a total inadequacy to the requirements* I consider that an officers hospital of at least 100 beds should be a *sine quâ non*

The hospital ships are working well, but up to date we have not been able to record the arrival of the *Princess of Wales* Her advent will be welcomed, as we have several cases fit for the voyage but which cannot be sent by an ordinary transport

Wynberg Dec 27th 1899

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan 11th, the Senior Vice President, Mr. H G HOWSE, being in the chair

Mr William Anderson, Mr Herbert W Page, and Mr Bernard Pitts made declarations in the terms of the oath prescribed by the Charter of 1800 and were admitted members of the Court of Examiners

The SENIOR VICE PRESIDENT reported that Mr Watson Cheyne had accepted an appointment as a consulting surgeon to the British forces in South Africa and had left England for the seat of war The Council expressed their cordial approval of Mr Watson Cheyne s patriotic action and granted him leave of absence for more than four consecutive meetings of the Council, according to the by laws

The SECRETARY reported the death on Dec 30th, 1899 at the age of 85 years of Sir James Paget, Bart, D C L, LL D, F R S, past President of the College, and stated that the College was represented by the Vice President and several members of Council and officials at the funeral service in Westminster Abbey

The following vote of condolence was carried —

> The Council hereby express their deep regret at the death of Sir James Paget Bart, D C L LL D F R S and their very sincere sympathy with his family in their loss The Council gratefully remember the many services rendered to the Royal College of Surgeons by Sir James Paget during his long association with it and they desire to record their appreciation not only of his eminence as a surgeon his ability as a teacher and his grace and eloquence as a speaker but also of his admirable personal character which won for him the warm regard of all who knew him The Council believe that no member of the surgical profession more fully enjoyed the confidence and esteem of his colleagues, they are assured that his loss will long be felt, and that his name will ever be placed in the foremost rank of those who have done good in their time and brought honour to their profession

The Council, on the recommendation of the Committee for General Purposes, directed the following reply should be sent to the mover and seconder of the fourth motion carried at the annual meeting of Fellows and Members in November —

> That as the date of the annual meeting of Fellows and Members is announced in the College Calendar and regularly advertised in the principal medical journals and as it is made known that any Member of the College may on application receive a copy of the annual report the Council are of opinion that sufficient notice is given of the meeting and that it is not necessary or desirable to further notify the date of the meeting or send a copy of the report through the post as suggested in Resolution No IV passed on Nov 16th, 1899

The Council decided to recognise for one year Cooke s School of Anatomy, Physiology, and Operative Surgery for the performance of the extra six months' dissections required for the Primary Fellowship Examination

The Council proceeded to consider a report from the Discipline Committee on the resolution carried at the annual meeting of Fellows and Members in November asking for a pronouncement of the Council that the acting as medical officer for a medical aid association was contrary to the declaration made by Fellows and Members on their admission The following motion was carried,

> The Council strongly disapprove of Fellows or Members of the College associating themselves with medical aid institutions which systematically canvass and advertise for the purpose of procuring patients.

This resolution was directed to be sent to the mover and seconder of the motion referred to

On the recommendation of the Discipline Committee it was resolved to send the following letter to the General Medical Council

> The Council of the Royal College of Surgeons of England have to inform the General Medical Council that their attention has from time to time been called to the conduct of certain persons whose names are entered on the Dentists Register with the description "In practice before July 22nd 1878.
>
> The persons in question adopt such titles and descriptions as R D S, L S C Eng, 'R D S Eng, L D S I, 'Registered by the Royal College of Surgeons thereby causing it to be inferred that they are connected with this College or the Scotch or the Irish College of Surgeons and thus infringing the privileges of the Licentiates in Dental Surgery of these Colleges
>
> The Council are of opinion that such conduct should be considered disgraceful conduct in a professional respect and that the persons in question should be deemed to have rendered themselves liable to removal from the Dentists Register under Section 13 of the Dentists Act, 1878
>
> The Council desire to call the attention of the General Medical Council to an advertisement wherein a dentist who is on the Register because he was in practice before July 22nd 1878, is described as R D S E. (Registered by the Royal College of Surgeons) Surgeon Dentist.
>
> The Council have to state that this gentleman is not a Licentiate in Dental Surgery of the Royal College of Surgeons of England, and they beg to request that the General Medical Council will cause inquiry to be made as to whether he is a Licentiate in Dental Surgery of the Royal College of Surgeons of Edinburgh and if it should be found that he is not, that the General Council will then call upon him to cease using a description implying that he is a Licentiate in Dental Surgery of one of those two colleges
>
> The Council further trust that the General Medical Council will take steps to make it known that the use of such misleading descriptions by persons registered under the Dentists Act will in future be regarded as 'disgraceful conduct in a professional respect and will render those using them liable to have their names erased from the Dentists Register under Section 13 of the Dentists Act 1878.

Mr William Anderson was elected a Member of the Board of Examiners in Dental Surgery

A letter was read from Mr J N C Davies Colley, resigning, owing to ill health, his membership of the Court of Examiners The resignation was accepted and the Council expressed their sympathy with him in his illness

The SENIOR VICE PRESIDENT said that the vacancies on the Court of Examiners and on the Board of Examiners in Dental Surgery thus occasioned would be filled up at the Ordinary Council on Feb 8th

The VICE PRESIDENTS announced that they had appointed Mr N C Macnamara Hunterian orator for 1901

The SECRETARY placed before the Council the new supplemental Charter under the Great Seal dated Dec 22nd, 1899

A letter was read from Mr Thomas Bryant reporting the proceedings of the General Medical Council at their late session, and the thanks of the Council were given to Mr Bryant for his services as the representative of the College on the General Medical Council

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 7128 births and 6474 deaths were registered during the week ending Jan 13th The annual rate of mortality in these towns, which had increased from 18 9 to 30 9 per 1000 in the six preceding weeks, declined again last week to 29 1 In London the rate was 33 3 per 1000, while it averaged 26 3 in the 32 provincial towns The lowest death rates in these towns were 15 6 in Burnley, 16 1 in Cardiff, 17 5 in Huddersfield, and 17 7 in Oldham, the highest rates were 34 6 in Liverpool, 37 4 in Croydon, 43 6 in Norwich, and 44 9 in Nottingham The 6474 deaths in these towns included 453 which were referred to the principal zymotic diseases, against 578, 623 and 506 in the three preceding weeks; of these 142 resulted from measles, 105 from whooping cough, 89 from diphtheria 56 from "fever" (principally enteric), 31 from diarrhœa, 27 from scarlet fever, and three from small pox No fatal case of any of these diseases occurred last week either in Derby or in Huddersfield, in the other towns they caused the lowest death rates in Brighton, Birkenhead and Burnley, and the highest rates in Wolverhampton, Salford, Preston, Blackburn and Sheffield The greatest mortality from measles occurred in Salford, Preston, Sheffield, Hull, and Sunderland; *from scarlet fever in* Blackburn, from whooping cough in Portsmouth, Wolverhampton, Leeds, and Newcastle, and from "fever" in Wolverhampton The 89 deaths from diphtheria included 49 in London seven in Sheffield, four in Leeds, and three in Portsmouth, in Bristol, in Swansea, in Leicester, and in Blackburn Three fatal cases of small pox were registered last week in Hull, but not one in any other of the 33 large towns There were 18 small pox patients under treatment in the Metropolitan Asylums

Hospitals on Saturday last, Jan. 13th, against five, seven, and eight in the three preceding weeks; 10 new cases were admitted during the week, against five, two, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2560, against numbers decreasing from 3578 to 2730 on the eight preceding Saturdays; 180 new cases were admitted during the week, against 209, 161, and 186 in the three preceding weeks. Influenza was certified as the primary cause of 340 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had increased from 324 to 1221 in the eight preceding weeks, declined again to 994 last week, but were 260 above the corrected average. The causes of 79, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Leeds, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 27·2 and 25·6 per 1000 in the two preceding weeks, further declined to 23·1 during the week ending Jan. 13th, and was 6·0 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 20·5 in Dundee and 20·6 in Greenock to 24·5 in Leith and 34·6 in Paisley. The 711 deaths in these towns included 20 which were referred to measles, 16 to diarrhœa, 14 to whooping-cough, six to "fever," five to diphtheria, and four to scarlet fever. In all 65 deaths resulted from these principal zymotic diseases, against 85 and 64 in the two preceding weeks. These 65 deaths were equal to an annual rate of 2·1 per 1000, which was slightly above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had decreased from 37 to 27 in the three preceding weeks, further [illegible] to 20 last week, and included 12 in Glasgow, four [illegible] Dundee, two in Paisley, and two in Greenock. The [illegible] from diarrhœa, which had been 17 in each of the two [illegible] weeks, declined last week to 16, of which seven [illegible] in Glasgow and three in Aberdeen. The fatal [illegible] of whooping-cough, which had been 17 and nine in the two preceding weeks, rose again to 14 last week, and included eight in Glasgow and two in Paisley. The deaths referred to different forms of "fever," which had been 10, six, and two in the three preceding weeks, rose again last week to six, of which four were registered in Glasgow. The fatal cases of diphtheria, which had been seven and three in the two preceding weeks, rose again to five last week, and included three in Glasgow, where three of the four deaths from scarlet fever were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 253 and 236 in the two preceding weeks, further declined to 203 last week, but were 47 above the number in the corresponding period of last year. The causes of 36, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 41·8 and 50·3 per 1000 in the two preceding weeks, declined again to 49·4 during the week ending Jan. 13th. During the past four weeks the death-rate in the city has averaged 46·0 per 1000, the rate during the same period being 33·9 in London and 22·2 in Edinburgh. The 331 deaths registered in Dublin during the week under notice were 6 below the number recorded in the preceding week, and included 31 which were referred to the principal zymotic diseases, against numbers decreasing from 72 to 18 in the eight preceding weeks. Of these 18 resulted from measles, five from "fever," three from diphtheria, three from diarrhœa, one from scarlet fever, and one from whooping-cough. These 31 deaths was equal to an annual rate of 4·6 per 1000, the zymotic death-rate during the same period being 2·0 in London and 0·7 in Edinburgh. The fatal cases of measles, which had declined from 24 to 10 in the three preceding weeks, rose again last week to 18. The deaths referred to different forms of "fever," which had been three, two, and five in the three preceding weeks, were again five last week. The three fatal cases of diphtheria were in excess of the average number in recent weeks. The deaths from diarrhœa, which had been five, one, and two in the three preceding weeks, rose again to three last week. The mortality from whooping-cough corresponded [illegible] preceding week. The 331 deaths in Dublin last week included 34 of infants under one year, and 108 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Six inquest cases and five deaths from violence were registered, and 110, or nearly a third, of the deaths occurred in public institutions. The causes of 13, or nearly 4 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1899.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during December in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·8 per 1000 of the population, estimated at 4,546,752 persons in the middle of the year. In the three preceding months the rates had been 11·2, 14·4, and 12·6 respectively. The rates were considerably below the average in Kensington, St. George Hanover-square, Westminster, Hampstead, St. Giles, and City of London; while they showed the largest excess in Fulham, Rotherhithe, Camberwell, Greenwich, Lewisham, and Plumstead sanitary areas. Six cases of small-pox were notified in London during December, two in Hackney, two in Limehouse, one in Shoreditch, and one in Whitechapel; eight small-pox patients were admitted into the Metropolitan Asylums Hospitals, and seven remained under treatment at the end of the month. The prevalence of scarlet fever showed a further decline from that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Strand, Holborn, Greenwich, Lewisham, and Plumstead. The Metropolitan Asylums Hospitals contained 2797 scarlet fever patients at the end of December, against 2836, 3406, and 3343 at the end of the three preceding months; the weekly admissions averaged 197, against 342, 426, and 304 in the three preceding months. The prevalence of diphtheria showed a slight decrease from that recorded in the preceding month; this disease was proportionally most prevalent in St. Martin-in-the-Fields, Shoreditch, St. Saviour Southwark, Newington, Camberwell, and Plumstead sanitary areas. There were 1679 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of December, against 1479, 1687, and 1718 at the end of the three preceding months; the weekly admissions averaged 184, against 210, 258, and 227 in the three preceding months. The prevalence of enteric fever in London showed a very considerable decline from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in St. James Westminster, Shoreditch, Bethnal Green, Limehouse, Poplar, and Newington. The Metropolitan Asylums Hospitals contained 406 enteric fever patients at the end of December, against 252, 341, and 460 at the end of the three preceding months; the weekly admissions averaged 52, against 41, 58, and 76 in the three preceding months. Erysipelas was proportionally most prevalent in Fulham, St. Pancras, St. Giles, St. Martin-in-the-Fields, Bethnal Green, and Rotherhithe sanitary areas. The 24 cases of puerperal fever included two each in Kensington, Hammersmith, Hampstead, Islington, Hackney, Bethnal Green, Poplar, and Battersea sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Dec. 30th the deaths of 9520 persons belonging to London were registered, equal to an annual rate of 27·3 per 1000, against 18·7, 18·5, and 17·6 in the three preceding months; this high death-rate was principally due to the prevalence of influenza. The lowest death-rates last month in the various sanitary areas were 15·6 in Hampstead, 17·4 in Stoke Newington, 20·7 in Lee, 21·0 in Hackney, and 21·5 in St. Martin-in-the-Fields; the highest rates were 34·7 in St. George Southwark, 34·8 in

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1899.

* Including 21 cases of membranous croup.

Including deaths from membranous croup.

Limehouse and in Bermondsey, 37·3 in Woolwich, and 40 0 in Westminster and in St. Olave Southwark. During the four weeks of December 744 deaths were referred to the principal zymotic diseases in London; of these, 1 resulted from small-pox, 238 from measles, 47 from scarlet fever, 207 from diphtheria, 115 from whooping-cough, 87 from enteric fever, 49 from diarrhœa, and not one either from typhus or from any ill-defined form of continued fever. These 744 deaths were equal to an annual rate of 2·1 per 1000, against 3 4, 1·8, and 1·9 in the three preceding months. The lowest death-rates from these diseases last month were recorded in Paddington, Kensington, Hampstead, St Luke, Lee, and Plumstead; and the highest rates in Fulham, Bethnal Green, St. Olave Southwark, Rotherhithe, Battersea, and Woolwich sanitary areas. The fatal case of small-pox belonged to Whitechapel sanitary area. The 238 deaths referred to measles were slightly below the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Fulham, St. Martin in-the-Fields, Whitechapel, St. George-in-the-East, Newington, and Battersea sanitary areas. The 47 fatal cases of scarlet-fever showed a marked decline from the corrected average number; the proportional fatality of this disease was highest in Fulham, St. James Westminster, Marylebone, Stoke Newington, Shoreditch, and St. Olave Southwark sanitary areas. The 207 deaths from diphtheria were four below the average number in the corresponding periods of the 10 preceding years; among the various sanitary areas this disease was proportionally most fatal in St George Southwark, St. Olave Southwark, Bermondsey, Rotherhithe, Camberwell, and Woolwich. The 115 fatal cases of whooping-cough were considerably below the corrected average number; this disease showed the highest proportional fatality in St. George Hanover-square, Hackney, Clerkenwell, Bethnal Green, Poplar, and Woolwich sanitary areas. The 87 deaths from enteric fever were largely in excess of the average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Hammersmith, Holborn, Limehouse, Newington, St. Olave Southwark, and Rotherhithe sanitary areas. The 49 fatal cases of diarrhœa were slightly below the average; among the various sanitary areas this disease was proportionately most fatal in St. James Westminster, Strand, St. George Southwark, and Woolwich In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during December was nearly 12 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to births registered, was equal to 187 per 1000. The lowest rates of infant mortality were recorded in Hampstead, St Luke, City of London, Mile End Old Town, Camberwell, and Plumstead; and the highest rates in Westminster, St. Martin-in the-Fields, Strand, Clerkenwell, St. Olave Southwark, and Rotherhithe sanitary areas.

Influenza was certified as the primary cause of 342 deaths in London last month, the corrected average number in the corresponding periods of the 10 preceding years being 100. Of these 342 deaths, 193, or more than one-half, were registered during the last week of the month. Among the various sanitary areas the greatest proportional mortality from influenza was registered in Paddington, St. George Hanover-square, Marylebone, Islington, St. Martin-in-the-Fields, and Lee. In addition to the 342 deaths directly attributed to influenza 3334 were referred to diseases of the respiratory organs during the four weeks ending Dec. 30th last, showing an excess of 1412 over the corrected average number.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Surgeons: H. M. Hart-Smith to the *Europa* for duty on voyage to Malta and afterwards to the *Ramillies*; C. Shepherd to the *Nile*; P. H. Boyden to the *Woodlark*; and J. A. L. Campbell to the *Vernon*.

ROYAL ARMY MEDICAL CORPS.

Captain P. H Whiston is appointed to the Medical Staff in the Home District. Lieutenant Colonel J. A Gormley has left for South Africa. Major J. M. Irwin is posted to the 8th Hussars and Captain R. C. Lewis to M Battery R H.A., for duty. Captain G. A. T. Bray has joined the Brigade Division Staff (43rd, 86th, and 87th Batteries). R.F.A, for service in South Africa. Lieutenant-Colonel W. W. Kenny has joined at Woolwich.

Major Arthur E. J. Croly is seconded for service on the Staff. Major Henry Martin, from the Seconded List, to be Major, vice A. E. J. Croly, seconded. Major Fausset M. Baker is placed on temporary half-pay on account of ill-health.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel William Harford Glover Phelps having attained the limit of age, is removed from the List of Officers of the Army Medical Reserve. Surgeon-Lieutenant-Colonel G. P. Bate having resigned his commission in the Militia ceases to belong to the Army Medical Reserve of Officers. Surgeon-Major Walter Culver James, Honourable Artillery Company of London, late Army Medical Reserve of Officers, is re-appointed with the rank of Surgeon-Major.

INDIA AND THE INDIAN MEDICAL SERVICES

Majors to be Lieutenant-Colonels: *Bombay Establishment:* George William Patrick Dennys, John William Unthank Macnamara, Joseph Sykes, and John Francis Tuohy. *Madras Establishment:* James Cort Marsden, Francis Casement Reeves, and John Leopold Poynder. *Bombay Establishment:* Charles Fancourt Willis. The Queen has approved of the retirement from the service of Lieutenant-Colonel Frederick Charles Barker, Bombay Establishment.

VOLUNTEER CORPS.

Artillery: The Tynemouth (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant J. Cromie to be Surgeon-Captain. *Royal Engineers:* 1st Lanarkshire: John Hammond Teacher to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Harry Roberts to be Surgeon-Lieutenant. 1st Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant H. S. Hughes resigns his commission: Thomas Thompson to be Surgeon-Lieutenant. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant A. Grant resigns his commission. 19th Middlesex: John Gallie Fraser to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

The Clyde: Surgeon-Lieutenant-Colonel P. F. Robertson, 1st Dumbartonshire Volunteer Rifle Corps, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: First Class Staff Sergeant Edmund William Herrington to be Surgeon-Lieutenant

TRANSVAAL WAR NOTES.

There is a movement on foot to use some of the islands off the north-west coast of Africa for the wounded to relieve the overcrowded and overtaxed depôts in South Africa. In Madeira large numbers could be accommodated by placing them not only in the environs of Funchal but in mountain villas as far as 2000 feet above the sea level. The climate of Madeira would be specially likely to benefit not only the wounded, but cases of dysentery, loss of blood, and, of course, pulmonary affections. The hotel-keepers have already made definite offers of entertainment. The Canary Islands, too, might be used in this connexion and we understand that Messrs. Elder, Dempster, and Co have offered to place a number of beds in their hotel at Las Palmas, free of expense, at the disposal of the authorities. Mr. Carlo Spaini, proprietor of the Grand Hotel Brunate, Como, has offered a reduction of 40 per cent. on the usual charges to all officers of the British army on their return from the seat of war who desire to reside at his hotel. The proprietors of the Grand Hotel, Arenzano, have also offered to place six rooms at their hotel free of all cost at the disposal of British officers wounded in the Transvaal.

Major C. R. Woods, R.A.M.C, is reported to have been wounded in the engagement at Ladysmith on Jan. 6th.

The Imperial Yeomanry Hospital Fund is receiving support from all parts of the country. Lieutenant-Colonel A. T. Sloggett is to act as military medical superintendent, and we understand that Dr. J. W. Washbourn, Mr. Raymond Johnson, and Mr. Newland Pedley will go out as medical officers. We understand that the National Fire Brigades Union has offered to provide an ambulance detachment of

28 men for the Imperial Yeomanry. This offer has been accepted. Towards the £50,000 necessary for carrying out the scheme £30,000 have been subscribed.

Surgeon Captain E. W. St. V. Ryan of the City Imperial Volunteers sails to day (Saturday) in the *Gaul*.

Dr. J. B. Coleman, F R C.P Irel., has been appointed to the staff of Lord Iveagh's Irish hospital. Fifteen orderlies for the hospital will be selected from the Royal Irish Constabulary.

Messrs. Offord and Sons have presented an ambulance containing several novel features to the Imperial Yeomanry for South Africa.

Messrs. Maw, Son, and Thompson's Roentgen ray operator, Mr. H C. W. Meredith, will go to the front with the City of London Imperial Volunteers.

The *Pavonia* arrived at Southampton on Jan 17th with sick and wounded, under the charge of Staff Surgeon Whelan, from South Africa Every possible arrangement was made for their comfort.

Major Maurice O'Connor Drury, R A.M.C, has been appointed to the charge of the Langman Hospital.

DEATHS IN THE SERVICES.

Inspector-General Edward Townsend Mortimer (retired), at Cromwell Houses, Southsea, in his sixty-sixth year. He joined the medical service of the Navy in March, 1856, and served as Assistant Surgeon during the China War from 1857 to 1862, being specially mentioned in despatches for his services at the capture of Canton. He was also present at the capture of the Peiho Forts and at the attack on the same in 1859, on which occasion he was thanked by the Commander-in-Chief for his services to the wounded, and promoted to Staff Surgeon (medal with three clasps) for his services in the Daphne during the Abyssinian War; he also received a medal and was promoted in 1876 to be Fleet Surgeon for the part he took at the capture on the East Coast of Africa of 18 slavers. As Medical Officer in charge of the Embassy he accompanied Rear-Admiral Gore Jones, C.B., on a Diplomatic Mission to the Queen of Madagascar, and as Deputy Inspector-General in charge of the Royal Naval Hospital, Hong-Kong, he received the thanks of the Government of that colony for acting as chairman of a Commission to inquire into the prevalence of fever there.

Mr. Robert Collum, M.D. Glasg., M R C P. Lond., M.R C.S. Eng., at his residence, Sutherland House, Surbiton, in his eighty-fourth year. He was formerly in the service of the Honourable East India Company and was Staff-Surgeon to Sir Charles Napier throughout the conquest of Scinde. Dr Collum rendered valuable services during the war and was mentioned in despatches of the battle of Meanee.

Correspondence.

"Audi alteram partem."

"THE MURMURS OF MITRAL STENOSIS."

To the Editors of THE LANCET.

SIRS,—It is a matter of pain and grief to me that Dr. Samways of Mentone considers that I have misrepresented his views in my article on Mitral Stenosis in the fifth volume of Professor Allbutt's "System of Medicine." I have no concern with the controversy between Dr. Samways and Dr. E. M. Brockbank. These two excellent observers must fight the battle out, *but I have a great concern in the portion of the* letter of Dr. Samways to THE LANCET of Jan. 6th, 1900, page 64, which virtually brings against me the serious charge that in my article in Professor Allbutt's "*System* of Medicine" I am guilty of misrepresentation.

In order to be clear let me quote the exact words which Dr. Samways employs. "He" (Dr. Brockbank) "states or, rather mis states, my theory thus: 'Samways believes that the abnormally powerful contraction of the auricle *prevents* regurgitation in compensated mitral stenosis and, further, that the auricle may even be strong enough to force blood into the ventricle after contraction of the latter has begun.' This extract *from* Allbutt's '*System of Medicine*' is unfortunate. I have never written anything about an 'abnormally powerful' contraction of the auricle and cannot help wishing that *Dr. Brockbank had looked up my original paper* and not argued from a digest which misrepresents me." Such is the serious charge of misrepresentation which *confronts me. Now for my defence.* I have *before me* what I take to be the original paper of Dr. Samways. It is a thesis thus dedicated: "A mon Président de Thèse Mons le Professeur Potain." It is entitled, "Le Rôle de l'Oreillette Gauche notamment dans le Rétrécissement Mitral, par D. W. Samways, Docteur en Médecine de la Faculté de Paris, M.D., M A., B.Ch. de Cambridge, D.Sc. de Londres, M R.C S, L R.C P. d'Angleterre, autrefois 'Fellow of St. John's College, Cambridge.'" The booklet is published in Paris by Steinheil, 1896.

The first chapter opens with these words: "Dans ce chapitre j'essaierai *de démontrer* que *dans le cas de rétrécissement* mitral pur, la compensation est maintenue, dans le plus grand nombre de cas, par l'hypertrophie de l'oreillette gauche associée à une prolongation de la systole auriculaire qui se continue durant une partie ou la totalité du temps pendant lequel le ventricule expulse son contenu." In Chapter II. in the first sentence are these words: "Dans le cas de rétrécissement mitral, si la contraction de l'oreillette hypertrophiée et non dilatré *empiète* sur celle du ventricule elle peut empêcher aveo succès la regurgitation venant du ventricule." I think that there is no necessity that I *should quote further*—the "*conclusions*" (page 71) repeat these views with certain additions. The immediate inferences that I formed were that, in the opinion of Dr. Samways, a compensated mitral stenosis was attended by (*a*) hyperthrophy of the muscle of the left auricle and (*b*) a prolongation of the (normal) auricular systole. It seemed to me that the inference was not only legitimate but necessary that there was in the cases mentioned an *abnormally powerful contraction of the left auricle.* It is to be remembered that this digest of what I took to be Dr. Samways's views was under the heading, "The Working of the Heart in Mitral Stenosis." It had nothing whatever to do with the morbid anatomy of the disease. This I had discussed in previous paragraphs, and I had given a summary of the observations of Dr. Samways on this part of the subject.

The *appearance* of the muscle *in hypertrophy* therefore was not under consideration, but its functions were. Surely there was no other course open to me but to describe the muscular contraction of the hypertropied muscle as "abnormally powerful." Hypertrophy of muscle cannot be normal *and the action of such hypertrophied muscle* must be abnormally powerful. Of course, by hypertrophy I mean strictly a condition in which the muscular elements have been *nourished more* than *normally* and have *consequently* increased in bulk. So also the protraction of the contraction noted by Dr. Samways can be nothing but abnormal and must indicate a muscular power in excess of the normal. If Dr. Samways contends that in compensated mitral stenosis the hypertrophy of the left auricle, the existence of which he admits, and the prolongation of its muscular contraction, which he also admits, do *not* indicate an abnormally powerful *contraction of* the auricle, then I must confess that I do not understand the meaning of his language, whether French or English, and I wonder whether there are any other competent observers who would or could understand it. The abnormally *powerful contraction* of the *left auricle* in cases of compensated mitral stenosis is proved by the clinical researches of many observers. I said in my article, which has been stigmatised as a misrepresenting digest by Dr. Samways, "He" (Dr. Samways) "shows from mechanical and experimental data that the *force* of the auricle, seeing that its active contraction is continued until the aortic valves are opened and a free outflow is permitted into the aorta, is adequate to prevent any reflux during the ventricular systole. It seems to me very probable that this view is correct. It affords a good explanation of the post-mortem appearances when a contracted mitral orifice, evidently of slow pathogenesis, is accompanied by a very small left ventricle. If mitral regurgitation had occurred in such a case the ventricular cavity would in all probability have become *dilated*." Be it well remembered that I was then considering the left auricle in the morbid condition of mitral stenosis. I had nothing in this relation to do with the normal action of the auricle in a state of health. The researches of Potain which had shown that the systole of the auricle overlapped the systole of the ventricle under physiological conditions—a conclusion which overrode our previous knowledge derived from the experimental evidence of Marey and Chauveau—I had previously called attention to.

In the study of the morbid anatomy of mitral stenosis I have found it very noteworthy that in some cases, especially when death has taken place in late childhood or early adolescence, there has been a great contrast in the size and appearance of the two ventricles. The left has been comparatively very small, whilst the right has been greatly hypertrophied and dilated. I have again and again in my clinical teaching shown the value of the recognition of this circumstance for the diagnosis of mitral stenosis. When there is little or no evidence of hypertrophy and dilatation of the *left* ventricle, but a consensus of physical signs showing disproportionate enlargement and abnormal force of the *right* ventricle, the existence of the condition of mitral stenosis is in high degree probable. The form of the obstructive lesion most frequently observed in these cases is that known as the "funnel mitral," though the "button-hole" transformation has been noted. It is a general consensus amongst observers that mitral stenosis is not a congenital malformation, but the result of a very slow and gradual morbid change. Seeing that the disease in the early stages, when the obstruction is comparatively slight, must involve the auriculo-ventricular aperture, it seems almost impossible that there should not be regurgitation. But if there had been regurgitation there would in all probability have ensued dilatation of the cavity of the ventricle, for mitral regurgitation in any notable degree is followed by enlargement of the ventricular cavity. As this cavity is observed to be small it is a fair inference that regurgitation has been prevented by some change making for compensation. An increased power of the normal muscle of the auricle, acting in the way which I understood Dr. Samways to suggest, would as I thought adequately explain the absence of dilatation of the left ventricle. Dr. Samways seems from the evidence of his letter in your columns to have a special objection to my use of the term "abnormally." He says "there is nothing 'abnormal' about the fact that the auricle under certain conditions of size should be able to exert a greater pressure on its contents than the ventricle can." He then enters into questions of physics, which, however germane to the question of the action of the auricle under physiological conditions, do not apply to its adaptation to conditions of disease. I suppose even Dr. Samways will admit that mitral stenosis is an abnormal state. The compensation which is maintained for weeks and months and years in this morbid condition is not effected without a disturbance of the normal conditions. The extra force necessary for the sufficient extrusion of blood through the narrowed mitral orifice must be afforded by some increase of power in the expulsive machinery behind the obstruction. Dr. Samways himself stated that this power came in the majority of cases because of the (abnormal?) increase of the muscle of the auricle or of the (abnormal?) protraction of its contraction. I have nothing further to say except to express the hope that those who have devoted much labour and much thought to the elucidation of the problems of mitral stenosis will not join with Dr. Samways in accusing me of misrepresentation. I think I have a right to complain in strong terms of protest of the language which he has employed against me.

I am, Sirs, yours faithfully,
A. ERNEST SANSOM, M.D., F.R.C.P. Lond.
London, Jan. 10th, 1900.

To the Editors of THE LANCET.

SIRS,—I am sorry to have misrepresented in my book on "The Murmurs of Mitral Disease" Dr. Samways' views on the power of the left auricle in mitral stenosis to prevent the regurgitation of blood after ventricular systole has commenced, by stating that in his theory the auricle contracts with abnormal force. After studying his theory I quoted Dr. Sansom's *résumé* of it, thinking that this put it impartially and concisely. If the auricle has only its normal force with which to overcome the action of the ventricle Dr. Samways' theory seems still less convincing. I also quoted Dr. Woods, who worked at the same subject from a similar point of view, as saying that he thought Dr. Samways' conclusions were absurd. The latter observer objects to this quotation as well, as being hard both on Dr. Woods and himself. He states in his letter to you that Dr. Woods considered his theory absurd because "there are no valves between the auricle and pulmonary veins, and he presumed that if the intra-auricular pressure tended to considerably increase, the leak towards those veins would prevent the rise of blood-pressure in the auricle which otherwise for physical and mathematical reasons must be produced." This objection is invalid, Dr. Samways urges, because there practically are valves in such a situation. Dr. Woods certainly gave this as his second reason for disputing the theory in question, but he also gave a third, and what seemed to be an important reason, which Dr. Samways does not refer to: "The mean radius of curvature of the contracted auricle is nothing like small enough to enable it to raise the pressure of its contents to anything approaching that of the ventricle when the relative thicknesses of the walls are taken into account." Whilst wishing to be perfectly fair to these gentlemen, whose opinions I respect even if I do not altogether agree with them, I am unable to see how I have been hard on them in my reference to their work.

Dr. Samways likens his views of the relative power of a contracting left auricle and ventricle in mitral stenosis to that of the two pistons of a Bramah press and asks, "Is it abnormal that the smaller piston of a Bramah press should be able to force up the larger?" To this question as put the obvious answer is: Yes, it is impossible for the smaller piston to force up the larger unless it be plunged with sufficient force to overcome the resistance of the larger piston. So in the same way it is impossible for an auricle to hold up the ventricle and prevent the regurgitation of blood, which I believe creates a crescendo murmur, unless the auricle contract with sufficient force to do this. That an auricle possesses such power at any time, especially in mitral stenosis when it is so often abnormally thin, has not been proved, nor is it probable that it does possess such power.

My theory of the causation of a crescendo murmur in mitral stenosis requires, as Dr. Samways says, that the jaws of the diseased valve should be stiff and close more slowly than in health. But it does not follow that the murmur should always be present when the valves are stiff, for I explain how the valves may be too rigid, especially towards the end of a case of mitral stenosis, for the failing ventricular contractions to close them at all, and how an ordinary systolic murmur of regurgitation is then heard (p. 16). And I also explain how a crescendo murmur may alternate with a systolic murmur in consecutive beats of a heart owing to the varying force of ventricular systole being able at one beat to close the rigid valve and at another feebler beat unable to do so. And although I believe that the stiffened mitral valve is a prime cause in the development of a crescendo murmur in mitral stenosis, I show how such a murmur may arise with a dilated valve when its curtains are of normal structure and mobility. As I go fully into these points in my book I will not take up your valuable space by repeating my arguments here, but respectfully refer Dr. Samways to them as being the best I am able to give in support of my theory that a crescendo murmur, whether it occurs at the mitral or aortic valve, in stenosis or dilatation, is always regurgitant in rhythm and caused by blood rushing through the valve which is abnormally late in closing.

I am, Sirs, yours faithfully,
E. M. BROCKBANK.
Manchester, Jan. 13th, 1900.

To the Editors of THE LANCET.

SIRS,—Dr. Brockbank has argued ably in support of the theory that the characteristic murmur of mitral stenosis is systolic in time, and it does not seem to me that the reasoning of Dr. Samways lends very strong support to the more generally accepted view. One case which I have seen, however, appears to prove that a murmur possessing the main features of the so-called presystolic murmur may occur before the systole of the auricle. Over a strongly beating but intermittent heart a loud presystolic murmur of sharply undulating, almost rattling, character was audible. When the intermission took place the murmur occurred in the early part of the pause and there was silence before the first sound of the next cardiac systole. In this case the murmur obviously occurred during the diastole of the ventricle.

Dr. Brockbank makes use of the different areas over which the diastolic and presystolic murmurs are audible to support the systolic theory. Since the presystolic murmur is best heard where the mitral systolic murmur is also best heard he suggests with some reason that both the so called presystolic and systolic murmurs owe their existence to regurgitation through the mitral orifice It seems to me to be a mistake, however, to consider that the diastolic murmurs are directly connected with stenosis of the mitral valve They appear to be merely varieties of that dull sound so frequently heard in the diastolic period of the cardiac beat in various morbid conditions of the heart that has been called not inappropriately "the third sound' Until the method of production of this "third sound" is clearly understood it seems to me that reference to the diastolic sounds of mitral stenosis will complicate rather than elucidate the question under discussion

I am, Sirs, yours faithfully,
Jan 12th 1900 THEODORE FISHER

OPERATIONS FOR ACUTE APPENDICITIS,

To the Editors of THE LANCET

SIRS,—I am glad to find that so careful and experienced a surgeon as Mr Keetley, in his letter in your last issue with reference to the points raised by Mr Moullin and myself, is substantially in accord with me with regard to the nature of the operation that should be performed for most cases of acute appendicitis With most of what Mr Keetley says I entirely agree He evidently recognises that it is not desirable to open the peritoneal cavity and the abscess without regard to the limiting adhesions This is the essential point which I ventured to urge in my letter in THE LANCET of Dec 30th, 1899 (p 1857) Although Mr Keetley claims that his method of operation may safely be adopted, even on the first day of an attack, he says later that he has no experience of any operation performed within the first 36 hours He does not tell us at what stage he does usually operate He objects to a rule of waiting until the fifth day So should I, and I have carefully refrained from laying down any such hard and fast rule, although I do think that the necessity for operation seldom arises before that period Each case must be judged on its own merits and the operation should, I think, be performed as soon as the surgeon believes that he can reach the abscess without opening the surrounding healthy (and absorbing) peritoneum Mr Keetley, with gentle sarcasm, seems to imply that I advocate letting the abscess alone indefinitely, but that is certainly not my practice The earliest period at which I have been able to open the abscess through the adherent peritoneum has been the third day, but *in most cases* the operation can, I believe, not be performed with safety at this period I see no objection to opening the non adherent peritoneum for purposes of gentle exploration if it be thought necessary I sometimes do this but I never open the abscess through the same incision I confess I do not see wherein the operation that Mr Keetley recommends differs essentially from that recommended and practised by myself and many other surgeons Mr Keetley probably goes a little more deeply into the iliac fossa than I should and probably operates somewhat earlier When he speaks of carrying his dissection "towards the pelvic brim' he certainly goes further than I should I should have thought that the manipulation necessary for such a deep dissection would have involved no little risk of rupturing the unopened intraperitoneal abscess (abscesses connected with the appendix are, of course, almost always intra peritoneal) The presence of a mass of inflamed tissues in the iliac fossa would not in my opinion, render such a deep dissection particularly easy Mr Keetley seems to think that his operation is peculiar in that thereby he goes to meet the pus instead of waiting for the pus to come to him. But if he will refer to my previous letter he will see that I speak of opening the adherent *peritoneum* I do not advocate waiting until the pus has come through the peritoneum Mr Keetley does not touch upon the interesting question which cases should be operated upon without regard to the adhesions That there are such cases no one I suppose would deny although for my own part I believe them to be rare It is not my intention however, to raise this question now

Mr Keetley expresses his belief that "more cases operated on from the fifth to the tenth day are fatal than any others But this I venture to think depends entirely upon what operation is done Fowler's[1] statistics of 49 cases operated upon from the fourth to the seventh day inclusive show 21 deaths, these were all cases of operation without regard to adhesions and would confirm Mr Keetley in his belief But the statistics from St Bartholomew's Hospital, which I quoted in my previous letter, of operations performed in some such manner as that advocated by Mr Keetley or by myself, tell strongly in the opposite direction But Mr Keetley apparently does not believe in statistics For my own part, I think they may be of much value, provided that they are accurate, that they deal with consecutive cases, and that they embrace a sufficiently large number of such cases

I am, Sirs, yours faithfully,
Wimpole-street, Jan 16th, 1900 JAMES BERRY

"DEATHS UNDER CHLOROFORM"

To the Editors of THE LANCET

SIRS—The letter of Lieutenant Clayton Lane, I M S, in THE LANCET of Jan 13th, p 132 expresses opinions exactly similar to those which appeared in a letter of mine in THE LANCET of July 1st 1899 p 53 Since the publication of that letter various letters have appeared in praise of Krohne and Sesemann's inhaler, none of which have convinced me Nor has conviction been carried to my mind by the bundle of pamphlets sent me last July by Messrs Krohne and Sesemann claiming innumerable advantages for their inhaler In fact, if a medical man believed all the statements in these pamphlets it would be easy for him to convince himself that administration of chloroform by any other method must be very little short of criminal

I am Sirs yours faithfully,
Plymouth Jan 14th 1900 C HAMILTON WHITEFORD

"THE CONFERENCE AT NEWCASTLE AND THE MIDWIFERY QUESTION."

To the Editors of THE LANCET

SIRS—Your correspondent Mr Charles E S Flemming has been good enough to lay before me in THE LANCET of Jan 13th, p 133, some points which have arisen from my letter which appeared in your issue of Jan 6th, and I thank him It is only through the bringing up and examination of other aspects of any vexed question that a right and final finding can be crystallised I have pleasure in answering him by means of the rough sketch of a scheme which I trust will also serve to explain still other points that might crop up

Scheme for the Working of Medical Practitioner plus Obstetric Nurse in Place of Midwife

1 Both medical practitioner and obstetric nurse to be responsible according to following arrangement and also according to further regulations which need not be introduced in this sketch

2. Patients to pay medical practitioner a fee for visiting of 3s. 6d to 7s 6d (subject to carefully fixing under revised scheme) In case of poverty the fee to be paid by parish

3. Obstetric nurse to attend *virtually* as medical practitioner's assistant at the labour and afterwards

4 Obstetric nurse to continue in attendance on labour and afterwards unless difficulties or complications arise when she shall send for *medical practitioner (just as midwives are expected to do and as assist*ant would do) If no complication or difficulty the obstetric nurse reports case to medical practitioner after a certain number of days and he will visit case

5. Medical practitioner's fee *plus* obstetric nurse's fee should be about equal former midwife's fee *plus* cost of common help usually required in addition Therefore disbursement of patient about same as under midwife system for visits of obstetric nurse should render supplementary help of paid woman less needed

6 Medical practitioner's fee shall be one for every class of case normal or complicated, the large percentage of normality making it well worth his while especially as he has his obstetric nurse under supervision and control in scheme rendering carelessness unlikely

7 Medical practitioners of districts to be appointed annually; to be advertised for and elected by boards of guardians or councils or *committees*

8. All patients employing obstetric nurses must consent to visit of appointed medical practitioner at least once They would be permitted to have consultation after this visit on paying for it in the ordinary way

The above is only intended as a sketch of fundamental principles which are only at the moment necessary to consider and only such details are put in as permit the principles to be advanced or as support them The following regulations as affecting the obstetric nurse are also merely intended as an indication of principles

Regulations as affecting Obstetric Nurse

1 Obstetric nurse shall not penetrate vulva with fingers, except perhaps under rare circumstances if licensed in training

---

[1] Annals of Surgery 1894, p. 505

2. Obstetric nurse shall only assist labour by external means, whether by manipulations, or medicines or instruments, or appliances
3. Aseptic principles, as taught, shall be carried out by obstetric nurse both as regards parts of patient, externally, and parts of obstetric nurse herself (hands, dress, appliances)
4. Obstetric nurse to douche passages of patient only after direction of medical practitioner, with approved appliances or instruments that are subject to medical practitioner's inspection on his visit.

As an answer to the question regarding responsibility urged by your correspondent, he will observe in the above scheme that an obstetric nurse would be subject to such control and disciplinary influence under an appointed medical practitioner as would render her malpractice rare and liable to the penalty of loss of certificate, to say the least. Nor can the point concerning fragment of placenta be properly advanced in the face of the above scheme. Any substitute for a qualified medical practitioner may leave behind a fragment of placenta—much more the ordinary or even registered midwife.—I am, Sirs, yours faithfully,

London, Jan. 13th, 1900. HAYDN BROWN.

"PRESCRIBING ALCOHOL *versus* OUR OWN INTERESTS."

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will grant me some space to reply to Dr. Coley's remarks upon my views In the course of a somewhat stormy controversial career I do not know that I have met with misrepresentations quite so complete as those with which he favours me in THE LANCET of Jan. 13th. He says: "According to him the way to secure sobriety for the human race some thousands of years hence is to let alcohol have its own way for the present and (with the aid of those beneficent eliminators of the unfit, poverty, and starvation, and tuberculosis, and crime) get rid of all who have 'an inborn capacity for delighting in it.'" May I ask Dr. Coley to quote, with due regard to the context, the passage in which I advocated views so atrocious and really so excessively silly? Giving my data, I made two statements of fact which I believe are incontrovertible—at any rate, they are incontroverted. The one that all free and civilised races are now temperate strictly in proportion to the extent they have been weeded out by alcohol; the other that in the future all such races will be temperate in like proportion unless certain measures (which I mentioned) were adopted. Having traced the past of an epidemic I endeavoured to forecast its future and to suggest a remedy. Dr. Coley thinks it right to inform a possibly horrified public that I advocate the spread of the disease. I am irresistibly reminded of the fat boy in "Pickwick" who was desirous of making the flesh creep.

He says, "Some of us may venture to doubt whether Weissmann's facts are sufficient to support his own theory." But, to quote the memorable words addressed by Sairey Gamp to Mrs. Prig, "Who deniges of it, Betsy?" I myself am of the opinion that Weissmann's doctrines are metaphysical nonsense and I cannot imagine why Dr. Coley will persist in attributing to me a belief in them. I hardly dare venture to suggest that he is perhaps belabouring the wrong philosopher; or to believe that this severe and confident critic has confused Galton's theory of the non-transmissibility of acquired characters with the fantastic superstructures for which alone Weissmann is responsible. If this surmise should unhappily prove correct—and really the more I think the more I believe it likely—Dr. Coley will find a deal of information, useful to the scientific critic, in the late Professor Romanes's book "Weissmannism."

May I suggest to him that the doubt he expresses is only an opinion and that mere opinions are not of the slightest value in science? If he will support his opinion with facts and arguments I on my part will cheerfully undertake to deal with them. For reasons I need not enter into this offer is not indicative of very great vanity. He concludes by saying, "But the inverted pyramid of inference which Dr. Reid has tried to balance upon Weissmann's dogma would topple over even if the foundation upon which he has rested it were firm as rock." But I have not tried to balance anything on Weissmann's dogma, whatever it may be. Moreover, my opinions were supported by facts and arguments. If instead of misrepresenting and then contradicting conclusions Dr. Coley will destroy the premises, I—well, I shall be infinitely surprised.

I am, Sirs, yours faithfully,
G. ARCHDALL REID.

Southsea, Jan. 15th, 1900

"DIPHTHERIA AND MILK-SUPPLY: A FILTHY HABIT."

To the Editors of THE LANCET.

SIRS,—I confirm Miss Williams's statement in THE LANCET of Jan. 13th as to the dirty and filthy habit of many milkers in the eastern counties who moisten their hands with saliva before seizing the teats in milking. It is quite possible that thus diphtheria bacilli might be introduced into the milk of a cow. On page 199 of Newman's "Bacteria" the suggestion is given of milk becoming contaminated with tubercle in like manner from a milker whilst suffering from tuberculosis.—I am, Sirs, yours faithfully,

WILLIAM H HEWLETT, M.D., D.P.H Aberd.

Wivenhoe, Essex, Jan. 15th, 1900.

"A CASE OF SUPRAPUBIC LITHOTOMY: REMOVAL OF TWO VESICAL CALCULI; RECOVERY."

To the Editors of THE LANCET.

SIRS,—Allow me to congratulate Mr. Vincent Jackson on his successful case of suprapubic lithotomy in a boy of eight years. At the same time I would like to ask why is it that such a case would hardly be remarked had it been treated by either litholapaxy or by lateral lithotomy? I only venture to ask you to permit me to occupy a small amount of your space in writing of this subject, because I have the advantage in forming an opinion of working neither in England nor India In treating successfully 30 cases of stone at varying ages between two years and 80 years—the calculi weighing from six grains to two ounces—I have employed every method and I heartily support Mr. Jackson in his plea for the right of the surgeon to select his operation. But I fear that Mr. Jackson's remark that "litholapaxy is a very easy operation while lateral lithotomy is not" may mislead. Mr. Reginald Harrison, whose keen clinical instinct always directs his knife and whose pen never wanders from the work that his knife has done, is not in favour of the suprapubic operation in children; and although in our art there is no finality it may yet be true that enough work has been done to show that while litholapaxy is seen at its best in children the suprapubic operation has proved itself of all methods in childhood the most dangerous.

I am, Sirs, yours faithfully,
W. A. MACKAY.

Rio Tinto Hospital, Huelva, Spain, January, 1900

"THE LESSON OF THE INFLUENZA EPIDEMIC."

To the Editors of THE LANCET.

SIRS,—There is one flaw in the counsels contained in the leading article on the above subject in THE LANCET of Jan. 13th and I fear it is a fatal one. If it be the duty of any person who has been attacked by influenza to seclude himself from contact with his fellows because he is infectious he is naturally entitled to ask to what extent he is to do so and for how long a time. How is his medical attendant to answer this question? If such a question be put in the case of small-pox or scarlet fever or enteric fever, and also, though not with precisely the same degree of certainty, in whooping-cough and measles, the attendant can reply until such or such symptoms or conditions have disappeared. The realisation of this result can, when it occurs, be recognised by the patient himself as well as it can by the medical attendant, except, perhaps, when the criterion of freedom from infection is a bacteriological one, as in the case of diphtheria, and it is upon the possibility of this recognition by the patient that his coöperation and that of his friends can be enlisted in maintaining the isolation which his medical attendant prescribes. But what is the criterion of freedom from infection in a person who has had influenza and to what extent and for how long is isolation to be prescribed? It is obvious that in such a case pure dogma, even if there were any base at all for it, is a dangerous aid on which to rest.

But there is another consideration which, apart from that just referred to, must make any attempt at isolation of influenza patients a counsel of perfection so far as the bulk of the public are concerned—it is the anomaly which the disease exhibits in its attacks. It is a fact with which, of course, the public are themselves familiar, that the disease will attack some members of a family and spare others, all of them being apparently equally liable to it and all of them in frequent contact with one another. A similar eccentricity in the case of the mild form of scarlet fever which has been so generally prevalent of late years creates the same difficulty in persuading the public of the need of isolating those who suffer from it. And it must always be so. Unless the public can recognise for themselves the criteria of infectibility it is not to be expected that they will have much respect for medical advice on the subject, or that medical men will expose themselves to be tripped up by the questions which are sure to be put to them if they counsel isolation.

I am, Sirs, yours faithfully,

Jan. 14th. A MEDICAL OFFICER OF HEALTH.

*** Our correspondent's letter points to certain obvious difficulties in the application of preventive measures to the spread of influenza. But he does not invalidate our contention that only by reasonable attempts at isolation can much good be done. The Clinical Society has reported that the disease may be conveyed by convalescents for 10 days For this period they should act as persons capable of conveying the disease. There are, of course, cases of doubtful diagnosis, but other cases are typical and the diagnosis in such is unmistakeable. That the infection of influenza is discriminating—that it takes effect on one and not another member of a family—is true But the same is true of all infections. While we admit that persons affected with influenza convey the disease, we must hold that for them to diffuse the poison they carry unnecessarily is to act improperly.—ED L.

PUBLIC HEALTH OF DUBLIN:

SCHOOLS IN THE SLUMS.

(FROM OUR SPECIAL SANITARY COMMISSIONER)

(Continued from Dec 30th, 1899, p 1869.)

As in the present instance children are the principal victims of the prevailing epidemic of measles, the condition of the schools and their surroundings are of especial interest. Taking one of the most central districts some account has been given of the great Roman Catholic school and of the Protestant Children's Home in Townsend street. With regard to the suburbs I have been shown a letter written by one of the former representatives in the House of Commons of the Irish Nationalist Party. This evidence does not come therefore from a bigoted Irish Protestant or from the "hateful Saxon," but from a patriotic Celt. The letter was written to one of the persons who helped me to collect information, and though not intended for publication is so typical and to the point that I cannot do better than reproduce some of the salient passages The writer says —

"I do think it was a very great act of charity to have THE LANCET making an inspection of some of the Dublin premises. He should be told that the sanitary accommodation of the schools would disgrace the interior of Africa. I have been at the Roman Catholic school at, ... (National school), and I can assure you that the grant should be withheld until proper sanitary arrangements were supplied' And this state of affairs prevails where churches are erected in the not remote neighbourhood costing £25,000, besides fabulous sums of money on their keep and the supply of vast palaces for 'holy poverty.' ...... I wish you could impress upon THE LANCET representative the *absolute necessity* that exists for the sanitary inspection of National schools. How are poor people to have a sanitary education if the practical lesson is not shown at school? In fact, why should the magistrates fine for want of cleanliness poor women who have not got the practical lesson when children at school, knowing, *as the magistrates* must do, that at the present moment the children are left derelict of appliances which distinguish the civilised from the savage peoples? If you only get this matter seen to you will have done the very greatest charity to the helpless poor and will certainly bring you and yours a blessing to all time.

This letter undoubtedly goes to the very root of the matter. What is the use of preaching the gospel of cleanliness, of saying that this and that should be done, if the great mass of the people have during their childhood received no object lessons while at school? It so happens that the majority of schools in Dublin are Roman Catholic schools; therefore, in criticising these schools it may appear as if an attack on the Roman Catholic party was intended. Even before I had time to say anything of a very pointed nature the Irish Roman Catholic press began to protest that it was wrong to ascribe the dirty habits of the Irish people to their religious convictions. Poverty, we were told, was the real cause, and this, of course, supplied a good pretext for political diatribes against the policy of England which had destroyed Irish industries and reduced the population to the verge of starvation. But industries flourish at Belfast; that town is a great centre of wealth and is also a great centre of Protestantism. Yet in the winter of 1897 and 1898 I likewise reported at length on the typhoid fever epidemics then prevailing in that town. Let those who accuse THE LANCET of seeking, under the cover of sanitary reform, to attack the Roman Catholic religion *read what was then published about Protestant Belfast* The trouble in Dublin is not so much the organic defects in the system of domestic drainage as the filthy habits of the people; and these habits are due in a great measure to the indifference or the technical incapacity of the teachers of the people. In this case they happen for the most part to be Roman Catholics. This I cannot *help*; I have *nothing* to do with their religious views and should doubtless have to make similar criticism in regard to Buddhist or Brahmin teachers if I had to deal with the prevalence of plague in India. There the poverty is even greater than in Ireland, and this is also the case in Turkey. Yet when visiting the cholera infected districts of Constantinople I had to render homage to the lessons of cleanliness taught by the Mahommedan religion, which insists that the faithful must wash first before they venture to pray. It is not for me in the columns of THE LANCET to discuss whether Mahommedanism is nearer to Divine truth than Christianity; but—and merely as a matter of fact—I must remark that a ritual which insists on ablutions before prayers is more useful to the cause of sanitation than a ritual which involves no such obligation In the Roman Catholic schools, though the children are taught to sing hymns and to pray, there are often no means provided for them to wash. The Irish may be poor, but if they nevertheless possess money to build big churches and schools they could also buy washing basins and a little soap. Enamelled basins that will not break are so cheap and soap is so cheap that there is no excuse whatever for not purchasing them. Yet the children coming from the schools—especially the industrial schools, where they have been boarders and therefore under the complete control of their teachers—are *often* covered with vermin and caked with dirt. This gross neglect can, should, and must be altered, and if nobody in Ireland will undertake the work then there ought to be inspectors from Whitehall to see that it is done. Every child on entering school should be examined and if not clean should at once be conducted to a properly appointed lavatory and made to wash. But in many cases such lavatories do not exist; and it is not too much to ask, in the face of the present appalling death rate, that all school grants should be withheld till such indispensable conveniences are provided and fully utilised.

Having visited two schools near the commercial centre of Dublin I next proceeded to visit two schools near the legal centre, the Law Courts, or the Four Courts as they are called, also selecting in this case both a Protestant and a Roman Catholic school. Little Strand-street leads to the "Sisters of the Faith St. Bride's Catholic Schools" The pavement of this street is very uneven and several of the houses have been abandoned. In one house, however, there were six families occupying five tenements and there was no closet at all on the premises; the inhabitants had to go to the backyard of the house next door. Here there were two water-closets, but the chains had been cut off from the flushing tanks, so that there was no flush except when provided by someone bringing a bucket of water to throw down. This was close to the walls of the school In the third house from the school the closet, the seat, and the floor and yard were covered with fæcal matter. Here there were many very poor tenants who paid from 1s. 8*d* to 2s 0*d*. rent weekly. The last and nearest house to the school was even more wretched and dirty. There were many old rags hanging out in the yard and some of the window panes were entirely broken away. On the other side of the school there was a large irregular-shaped yard. Piled up against the wall of the school there stood a great manure heap from which dark-brown liquid manure issued and formed stinking pools on the unpaved porous ground. The emanations from the polluted subsoil would be drawn into the school by the greater heat prevailing in the class rooms. In this yard there is also a stable, a fearful closet, and on one side a tenement house where wretched ragged people dwell. This touches the wall of the school. My request to visit the interior of the school was received with much trepidation and hesitation. Though I was accompanied by a municipal officer still it was thought that I must obtain special permission. However, I was able to ascertain that there was no lavatory for the boys and that the principal schoolroom was dark and ill-ventilated. Within some two or three yards of the windows was a high black wall. It had never occurred to the sisters in charge that by whitewashing this wall a better light would be reflected into the school, and that this would be more wholesome and cheaper than burning gas in the daytime. Here, again, was an instance of the absence of technical knowledge. But lest I should be once more accused of attacking Roman Catholics because of their religious convictions, let me say that I had here an opportunity of noting the politeness and courtesy of some of the school-children Indeed, whatever may be the defects of education in Roman Catholic schools, so far as my personal observation goes I have always found that they succeed better in teaching manners, in inculcating an appreciation of the courtesies that render life so much more pleasant and social intercourse so much more refined, than is the case in regard to Protestant schools.

It is doubtless necessary that schools should be built in populous districts so as to be close to the homes of the children, but this renders the erection of a healthy building very difficult. The amount of ground secured should be sufficient to allow an open space providing a good sweep of air and an ample provision of light all round the building. This is not the case in regard to St. Bride's Catholic Schools. On one side there is the black wall already described; on the other the very poor, narrow, wretched street, buildings on the third side, and the foul yard with the manure heap saturating the school walls on the fourth side. Nor are there any recreation grounds. The children arrive, some at 9 o'clock, but most of them at 10 o'clock, and they leave at 2 o'clock. Therefore, there is no break, no recreation or meal hour. This is too long and yet not long enough. From two to three hours at a time in a class-room is quite sufficient for young children; then there should be a break for a meal or for a healthy romp in the open air, and the pupils could work again for another two hours or so, thus attending their classes for at least five hours a day. To attempt to crowd the whole of the education given into one long sitting is not judicious either from the educational or from the sanitary point of view. This is done doubtless to avoid the difficulty of having to feed the children; but, on the other hand, the greatest advantage would be derived from the establishment on the French model of a *cantine scholaire*, where for a penny or so a wholesome bowl of soup could be provided. Such catering being on wholesale principles would cost much less than the meagre food purchased for them retail by their parents. Considering that the population of Dublin is, in the main, underfed, this question of school meals for the children of the poor is of the utmost importance. As it is, the children are not only ill-fed, but the air that they breathe is, in a measure, deprived of its strengthening qualities by bad ventilation, by the want of the purifying effects of direct sunlight, and by the foul emanations from the surrounding slums. No wonder that so many of these children should be struck down by the prevailing epidemics.

The large court overlooked from one side of the school gives on to a twisting narrow alley. This alley is paved with loose-fitting cobble stones which do not protect the subsoil from contamination. All along the alley there are manure, garbage, and dust heaps. Old shanties in ruinous condition abound on both sides of the alley. There is one very dark place where some poor people are employed to cut wood. Black mud oozes up on all sides and the earth is covered with decomposing organic matter. The other end of the alley abuts on to East Arran-street where there is a street market, and the costermongers get rid of their fish-heads and offal by throwing them into this comparatively unfrequented alley. Thus this refuse gravitates towards the school walls and helps to pollute the air the children have to breathe. Facing the alley that winds round the school, but on the opposite side of East Arran-street, is Water-alley. Here the houses are in a dilapidated condition, the windows for the most part are broken and the framework shattered. In the yards of these houses there are strange wooden shanties built up as rough stables for donkeys and other animals. Outside manure heaps accumulate and portions of the manure are scattered for a considerable distance around. Bare-footed children tread upon all this filth.

In Craig's-building, Charles-street, hard by, I penetrated into one of the houses. There was a twisting, narrow, dark passage with pools of filth on the stair landing. Below there was a very small yard. Here stood a closet under some bedroom windows. The pan was full and overflowing with fæcal matter, the drain was evidently blocked, and the foulest odours entered freely into the house. The other houses near at hand were all filthy and dilapidated. Pill-lane (which had such an awful reputation that its name has been altered to Chancery-street), Greek-street, Beresford-street, and Little Mary's-street all contain many houses unfit for human habitation; indeed, some portion of Greek-street has been condemned and already pulled down, but some of the condemned houses that still remain are inhabited. Here and there the manure from the backyards has been kicked, carried, and blown as far as the street. Yet some of these houses were in former years well tenanted. They have broad staircases and porched doors. The fact that these houses were originally built for single and well-to-do families renders them the more unsuitable for tenement dwellings. A little further on I reached Lurgan street, where there is a Protestant boys' school close to the barracks. There was a fusty, unpleasant, close smell when I entered this school which suggested insufficient ventilation. There was, however, a large yard behind where the children could play and breathe the outer air. Here at the farthest extremity from the building were trough closets made of tiles so that the boys must stand. This continental system has at least the advantage of being easier to wash out and with careless people it is more safe. There are some 200 children in this school and they likewise suffer from their surroundings. On one side they have the barracks, behind the large yard, and in front the street, but on the other side and very close is an objectionable tenement house. The second next house has been condemned and its inhabitants have left, consequently the neighbours throw their rubbish and refuse into the yard and ruins and there is no one to remove it. One of the closets gives off such foul odours that they reach the school and sometimes necessitate the closing of the school windows on that side. In the yard of the tenement house nearest to the school and within 15 feet of one of the school windows the closet is in a filthy and neglected condition; fæcal matter lies on the floor in front of the seat and other persons have defecated in the hall passage of the house itself. A considerable amount of linen is hung out to dry above this foul dirt. As for the play yard of the school itself, though clean, it is not suitably paved, for it has cobbles instead of asphalt, and there are chemical works at the back of the yard. Thus it will be seen that the surroundings of this Protestant school, like those of the Roman Catholic school, are altogether unfavourable and also tend to contaminate the air the children breathe.

Retracing my steps and going in the direction of Sackville-street I passed by Cambell-court. Here a number of scavengers in the employ of the corporation were sweeping out this court. Nevertheless, in broad daylight at 1 o'clock in the afternoon a man urinated against the wall at the entrance of the court, and this in the presence of the municipal employés. No one protested. The fact is that there are hardly any sanitary conveniences provided in the poor quarters of Dublin, and it will be a long time before the people are taught not to relieve themselves in the streets, courts, and alleys. In Taafe's-court there is a public stand-up tap or fountain. It is surrounded with fæcal matter. People come and empty slop pails into the gully under the water-tap On the other hand, those who come to fetch water tread in the dirt and are likely to soil the pails or pitchers in which they take the water they are about to drink. The cottages in this court have been condemned and are now uninhabited. Before these people left the court there was very much more filth round the tap, yet what I saw was bad enough. Then I reached a local Petticoat-lane, which is the second-hand clothes market, and in consequence of the insanitary conditions it is doubtless a prolific source of the spread of disease. In Sampson-lane there is a whole row of what by courtesy are called slaughter-houses, though they are utterly devoid of any sort of suitable arrangement. Cobble pavement prevails, the animals are slaughtered in mere shanties, blood and offal reaches the street, and no measure whatsoever is taken to prevent the contamination of the subsoil. There is a whole row of these slaughter-shanties, and immediately opposite, overlooking them and only separated from all the offal by the narrow street, there is a row of inhabited dwelling-houses. There is also a court facing the slaughter houses which is full of manure piled under a splendid metal plate put up by the corporation announcing that anyone who deposits refuse on this spot will be prosecuted. At the other end of this lane, which abounds in slaughter-shanties, there are a market and many butchers' shops. At last I reached Sackville street and I would certainly advise the tourist who is brought to this magnificent thoroughfare and told that Dublin is a fine town to turn aside and wander through the small streets between Sackville street, the Four Courts, and the barracks at the foot of Constitution-hill. For sordid misery, dilapidation, and dirt it would be difficult to find anything more depressing and degrading.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Gift of a Botanical Laboratory to University College, Liverpool.

MR W. P. HARTLEY of Aintree has offered the sum of £12,000 to the governors of University College towards the erection of a new botanical laboratory and museum. The College is in great need of a suitable building for botanical purposes, as under present arrangements it is impossible to exhibit adequately the materials collected in the limited space at the disposal of the professor of botany. The botanical laboratories and museum are at present housed in the old building in Ashton street, and consist of a laboratory capable of accommodating 30 junior students, a smaller advanced laboratory, a professor's room, and two rooms which serve as a museum. The museum contains a teaching series of cryptogams and phanerogams and a large herbarium of British and foreign plants Mr. Hartley's munificent donation will enable the governors of University College to provide accommodation for the numerous requirements of the botanical department and will also promote the completion of the buildings necessary to form a quadrangle of noble proportions. The chair of botany, which is so worthily occupied by Professor Harvey Gibson, was founded in 1888, principally by the munificence of Dr. Holbrook Gaskell, who contributed the sum of £5000, to which he added a further sum of £1000 in 1894.

The Liverpool Hospitals and the Invalids from the Seat of War.

The committee of the Royal Infirmary at their last meeting, in answer to the appeal of the War Office which has been made to them in common with the managers of other hospitals, resolved in addition to the 12 beds previously offered, to make arrangements for the reception of 18 more invalided soldiers belonging to the Liverpool district free of all cost to the Government. To enable this to be done without prejudice to those for whom the charity was intended it was determined to convert the large entertainment room into a ward This course will entail little trouble and expense beyond the increased cost of staff and maintenance due to the larger number to be provided for The Royal Southern Hospital and the Northern Hospital will also provide some beds for a similar purpose; the latter have offered to provide eight beds at a charge of 2*s* a day The Stanley Hospital authorities have decided not to take any steps in the matter until they are in receipt of further information on the subject.

The Warrington Infectious Diseases Hospital.

The Warrington Town Council have passed a resolution decreeing that alterations involving an expenditure of £10 000 should be made in the Warrington Infectious Diseases Hospital.

Influenza in Liverpool.

The medical officer of health reports that the death-rate of the city is exceptionally high, owing apparently to the presence of influenza, although influenza did not appear in the statistics as the actual cause of death, except in a limited number of cases. Dr. Hope points out the valuable work which has been done by the female inspectors in improving the health of poor localities. In the matter of the management of infants very useful hints are given by them to ignorant parents.

The Proposed County Asylum for Inebriates.

A conference between representatives of the Lancashire County Council and the county boroughs will be held at the County Hall, Preston, on Jan. 29th to settle the terms of the Bill which is to be promoted next session for providing a county asylum for inebriates

The Microbe of "Pink-eye" in Horses.

Dr. H. E Annett, of the Liverpool School of Tropical Diseases, has been conducting investigations into the prevalence of "pink eye" in Liverpool horses and has found, he believes, in every case the same bacillus The disease had been making such serious ravages among horses in Liverpool that the Cart-owners' Association sought the assistance of Professor McFadyean, who has arrived here from London to investigate the disease on the spot Should the discovery of the microbe prove to be an accomplished fact the Liverpool School of Tropical Diseases is to be congratulated in that it will have been the means of minimising the widespread ravages of this formidable disease among horses throughout the country. Dr. Annett's experiments are to be continued

Jan. 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Housing of the Working Classes.

AT the meeting of the Manchester City Council on Jan. 3rd a report from the Sanitary Committee was adopted which recommended the purchase of 237 acres of land at Higher Blackley to be used for purposes under the Housing of the Working Classes Act and the Allotments Acts. In moving its adoption Alderman Walton Smith, the chairman of the committee, spoke of the work done during the past 14 years in the way of demolishing back-to-back houses and insanitary buildings generally and of the difficulties experienced in finding suitable accommodation for the people who had been displaced Objection was taken to the purchase, as the distance was four miles from the city, but this was met by the statement that by the time the houses were built and the land laid out there would be railway and tramway facilities, so that working men would be able to get to and from their work without difficulty There is some difference of opinion as to whether a workman should live near his work or at a distance, and it is satisfactory to know that one member of the council, well known for his acquaintance with the habits of the working classes, said that those who lived away attended their work better than those living near to it in the centre of the town This recalls the mistake made when the assize courts were built in Strangeways. It was thought that the judges, tired with the day's work in court, would be glad to pass along a corridor into the beautiful house adjoining which had been built for their entertainment But no; they wanted to get away for a few hours from the scene of their labours and to breathe a fresher air, so that now they make no use of their lodgings in Strangeways The better sort of working men will be only too glad of a change from the stuffy town, while the boon to their wives and children will be priceless. And in these days we cannot afford to neglect anything that will help to bring up the coming race in health and vigour.

Street Explosion in Manchester.

We are reminded from time to time that all of our nineteenth-century conveniences bring with them their special dangers. Not long ago a high pressure main gave way in Strangeways, causing a large upheaval of the ground, and some time afterwards a sewer gave way in Oxford street threatening, as one of the local papers puts it, "a number of innocent passers by with the fate of Korah, Dathan, and Abiram." Occasional upheavals on a comparatively small scale have occurred in connexion with the electric supply and on Jan. 5th a terrific report startled the people near the Royal Exchange, the flags in front of the building being lifted for a distance of 20 yards, while, as an eye-witness says, "in a few seconds a sheet of flame at least 20 or 30 feet high sprang from the pavement." It is extraordinary, and as some say "little short of miraculous," that no one was hurt, for these flags are crowded on Friday afternoons. There were, however, some narrow escapes, one gentleman having his hat blown across the road though he felt no shock. There are always satisfactory explanations of the why and the wherefore, but they come a little late. Mr. Wordingham, the city electrical engineer, is said to have explained that "the accident was due to the fact that the old-fashioned rubber cables are liable under certain conditions to portions of the rubber distilling from excessive heat" Another account states that it was caused by defective insulation, "the current finding its way out through a weak spot and instantly converting a considerable length of the indiarubber covering into inflammable vapours which took fire." It shows how progressive and yet how imperfect our practical knowledge is that these cables, laid a comparatively short time since, with the sanction, presumably, of the late Dr. John Hopkinson, who represented the foremost science of the day, should so soon have become "old-fashioned" and discarded and that for some time their removal has been going on. The explosion took place in a comparatively small section that was awaiting removal. Mr. Wordingham is said to have stated that "the new kind of cable was of a material that would render a repetition of these explosions absolutely impossible when the relaying in the city was complete." This is satisfactory so far as it goes, but such predictions are not always fulfilled. As the *Manchester Courier* says, "Nothing would excite more general surprise than the absence of excavations for two days together in any of our main streets" for something connected with the gas pipes, water pipes, sewers, or electric cables.

A Fatal Christmas Feast.

As everyone knows, our national festivals are made the occasions by some of the baser sort for disgusting orgies, though it is comparatively rare for the results of their abuse to be the subject of a coroner's inquest. But on Jan. 2nd Mr. Smelt, the city coroner, held an inquiry concerning the death of a woman from Salford who, with her husband, was spending New Year's Eve with an aunt in Hulme. She had complained of not feeling very well, but after taking some tea and whisky seemed better, and during the evening took some tinned salmon, tinned lobster, bread-and-butter, sweet cake, two glasses of claret, and a bottle of stout. She also sang a song, but had to go to bed, and "soon after midnight, whilst the company were still welcoming the new year with liquor and music, she died." Besides this woman there were ten people in the house all drunk. Mr. Heslop made a post-mortem examination of the body and after his evidence the jury returned a verdict of "Death from syncope arising from heart disease and excessive eating and drinking," while Mr. Smelt characterised the case as one of the most disgraceful that had ever come before him. We hear a great deal that is true about the good qualities and the intelligence of our working classes, but not perhaps quite as much as it is well for us to know of the large leaven that exists of those whose civilisation is little above that of the lowest savages. The problem of their rescue from a condition that does not speak well for the practical results of our educational methods is not one to be entered on here, but it is saddening and disquieting to think that in close proximity to, yet untouched by, the knowledge, the culture, and refinement of the day there are numbers of our people whose moral and intellectual plane is scarcely above that of the "brutes that perish."

Washhouses in Congested Districts.

At the last meeting of the Manchester City Council one of the members asked what had been done with regard to his suggestion made some months ago to the Baths and Washhouses Committee that small washhouses should be provided in the congested districts of the city. The chairman replied that a special sub-committee had been appointed to consider the question and would be called together early in the year. This question is not new. It was brought before the committee years ago. The boon to the poor women living in back streets in crowded houses with scant accommodation for washing themselves and their children would be most valuable. They have not the courage to go to the palatial public baths with their grimy little offspring but would gladly take them to a cottage differing little from those in which they dwell. This matter has often been pressed on the committee, as the chairman well knows. But some of the council are ambitious and wish the baths to be noble buildings "worthy of a great city," as if anything would for long be decorative where smoke is allowed so much of its own sweet way.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Hospital Accommodation for Wounded Soldiers in Scotland.

THE Board of Directors of the Crichton Royal Institution, Dumfries, have offered to take in 10 wounded soldiers from South Africa, preferably men suffering from nervous disorders. The managers of Campbeltown and district Cottage Hospital have offered to the War Office the free use of five beds in the hospital for the accommodation of wounded or invalid soldiers. The Red Cross Society in Glasgow has suggested to the Health Committee of the Glasgow Town Council that a portion of the new hospital at Ruchill in the Maryhill district of Glasgow should be offered to the Government for the accommodation of soldiers from the front. The committee forthwith agreed to offer the Government the use of the eastern part of the hospital consisting of eight pavilions where 500 soldiers could be accommodated. It is understood that the Red Cross Society undertake to provide the medical men and nurses It is expected that the hospital will be ready for use by the end of February or the beginning of March. Two beds have been offered in the Castle Douglas Diamond Jubilee Hospital for the accommodation of wounded soldiers, preference being given to those of the territorial regiment, the King's Own Scottish Borderers.

Typhoid Fever in Ayr.

Six fresh cases of typhoid fever have been notified within the last few days in Ayr, bringing the total number up to 176 on Jan. 16th.

Urban Mortality in Scotland in 1899.

An examination of the monthly returns as to the eight principal towns of Scotland, published by the Registrar-General and the issue of which for last year has just been completed, shows that the total general mortality in the eight towns together was 32,430, which on an estimated aggregate population of 1,587,414 gives a death-rate for 1899 of 20·43 per 1000 living inhabitants. Of the total 32,430 deaths, 15,828 occurred in Glasgow (the largest of the eight towns), 5859 in Edinburgh, 3189 in Dundee, 2719 in Aberdeen, 1410 in Leith, 1509 in Paisley, 1321 in Greenock, and 595 in Perth. This brings out the respective death-rates in the towns individually as follows:—Glasgow, 20·16 per 1000; Edinburgh, 19·60; Dundee, 19·20; Aberdeen, 19·06; Leith, 18·22; Paisley, 19·49; Greenock, 21·70; and Perth, 19·37. Of the whole 32,430 deaths 12,111, or 37·34 per cent, were of children under five years of age. In Perth 24·37 per cent of the persons who died were under five years of age, in Edinburgh 32·19, in Paisley 35·39, in Aberdeen 36·81, in Dundee 37·91, in Glasgow 39·15, in Greenock 41·33, and in Leith 42·13 Miasmatic diseases caused 3062 deaths in the eight towns collectively, or 9·4 per cent. of the whole number. In January, measles and whooping-cough were prevalent in Aberdeen, Edinburgh, and Leith. In February, whooping-cough prevailed in the same three towns, measles in Aberdeen, and influenza in Edinburgh. In March, influenza was marked in Edinburgh and Aberdeen, whooping-cough in Edinburgh and Leith, and measles in Aberdeen. In April measles still prevailed in Aberdeen and whooping-cough in Leith. In May and June whooping cough continued to prevail in Leith and measles was marked in July. Measles also prevailed in Glasgow in June, July, and August In September fever prevailed in Paisley. There was an abnormal mortality from measles in October in Glasgow, Leith, and Greenock. The same was the case in Greenock and Perth in November, in which month also whooping-cough prevailed in Perth. In December the average rate of mortality from miasmatic diseases was exceeded in Paisley owing to the prevalence of measles and whooping-cough, in Greenock because of measles, and in Perth because of measles, scarlet fever, and whooping-cough. The deaths for the year for the eight towns collectively from inflammatory affections of the respiratory organs (not including pulmonary phthisis and whooping cough) amounted to 6267 or 19 3 per cent of the whole Those from pulmonary phthisis alone numbered 3033 or 9 4 per cent The mean temperature for the year was 47 8° F and the mean rainfall 36 99 inches During the year the death was recorded of a widow aged 101 years Some particulars are also given as to 44 selected smaller town districts with a united population of 721 801 In these collectively the general mortality amounted to 13 090, or 18 13 per 1000 inhabitants 3835 of the deaths took place in the first quarter

Aberdeen University Court

At a meeting of this body held last week it was agreed that the classes in Latin under graduation class standard should be discontinued The annual accounts of the University were submitted by Professor Hay, who said that the young and growing Faculty of Science and the University library were inadequately provided for Otherwise the surplus past and expected, was fairly good and the prospects including those of the completion of the building extension scheme, were not unsatisfactory An endeavour is being made to arrange the difficulty as to the site for the new Greyfriars Church in connexion with the extension of the University buildings

Jan. 16th

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Health of Dublin

THE health of Dublin shows no improvement, last week again 110 deaths from respiratory diseases were registered It has been officially announced that His Excellency the Lord Lieutenant has been in communication with the Local Government Board of Ireland on the steps which should be taken for dealing as promptly as possible with the present unhealthy condition of Dublin The matter is forming the subject of a joint inquiry by the inspectors of the Local Government Board and the chief public health officer of the Corporation A letter dated Jan 13th was addressed by the Local Government Board to the superintendent medical officer of health of the city, suggesting various sanitary precautions conveying a warning to the public in reference to the highly infectious nature of the influenza now prevailing and promising the approval of the Board for any temporary addition which the Public Health Committee might think it necessary to make to their staff of sanitary sub officers and dairy inspectors A letter has appeared in the morning papers from Sir Charles Cameron informing the public that although influenza is not notifiable under the provisions of the Infectious Diseases Notification Act it is highly contagious and persons suffering from it should be carefully isolated To judge by the leading articles and letters which now appear daily in the journals both the public and the authorities are at last becoming alive to the appalling state of things as regards the death rate which now exists in Dublin

Mater Misericordiæ Hospital, Dublin

The authorities of the Mater Misericordiæ Hospital have guaranteed that at least 30 beds shall be available there for wounded patients who may return to Dublin from our armies in South Africa The hospital is the largest in Ireland and is dependent altogether on the donations and bequests of Irish people—receiving no Government grants whatever

The Irish Hospital for South Africa

In addition to Sir William Thomson and Mr George Stoker Dr J B Coleman of Dublin has been appointed to the staff of Lord Iveagh s Irish hospital for South Africa Dr Coleman, who is a physician to the Richmond Hospital, was formerly a house surgeon at the Mater Misericordiæ Hospital

Death of Dr S R Mason of Dublin

Dr S P Mason of Merrion square Dublin died rather uddenly on the morning of Jan 9th His health was known to be bad for the last few years but his immediate death was not at all anticipated He was an M D of the Dublin University, a Fellow of the Royal College of Surgeons in Ireland, and formerly a Master of the Coombe Hospital. He filled the chair of Midwifery at the Royal College of Surgeons in Ireland for some years His death at the early age of 43 years has been a cause of much regret to his many friends.

Coleraine Cottage Hospital

At the annual meeting of the supporters of this charity, held on Jan 9th, it was reported that the receipts for the past year were £553 16s 3d, and the expenditure £362 18s 4d The building, which was closed from April until December for enlargement and improvement, was re opened rent free, and the re furnishing will soon be complete 19 patients were admitted and there were 35 extern cases

Death of Dr R L Hunter of Larne

I regret to announce the death at his residence, Larne, co Antrim of Dr R L Hunter, on Jan 12th, at the age of 68 years. Educated at the Belfast Queen's College, he graduated M D of the Queen s University in 1868 After acting as an assistant in England he was engaged as a surgeon during the Franco Prussian War He escaped from Metz during the great siege of that place and went to America, whence he returned to his native district and for the last 30 years has practised in Larne At different times he was Admiralty surgeon, police surgeon, and attendant to the coastguards and naval reserve His health had been gradually failing for the past 12 months He had an extensive practice and enjoyed the respect of a large circle of friends

Ulster Medical Society.

The usual monthly meeting was held on Jan 10th at the Museum, Belfast, but owing to the great epidemic of illness there was not as large an attendance as usual Professor W. H Thompson read a paper on Protamines and their Cleavage Products and Physiological Effects, and Dr Kirk brought forward a communication on Fractures of the Neck of the Radius

The Influenza Epidemic

The epidemic of influenza is still raging all over the North of Ireland, increasing the death rate, causing great inconvenience in business and giving medical men an immense amount of work

Death of Dr Stephen O Sullivan Professor of Surgery in the Queen s College, Cork

Cork has been visited by a very severe epidemic of influenza During the week ending Dec 23rd, 1899, the mortality rose to over 50 per 1000 The resources of undertakers and of officials of cemeteries have been taxed to the utmost The local members of the medical profession have supplied their quota to the sufferers Already something like 25 per cent of medical practitioners have been prostrated by the disease, whilst the others have been kept rushing from patient to patient Professor O Sullivan was confined to his house for about three weeks, suffering from a severe attack and, believing himself to be then sufficiently recovered, he resumed the practice of his profession For many years he had been suffering from asthma and chronic bronchitis and the attack of influenza had so undermined his constitution that a relapse soon resulted in pneumonia which proved fatal in a few days The news of his death, which occurred on Jan 8th, was heard with great regret, not alone by members of the profession but also by the citizens at large He obtained the degree of M D at the Queen's University in 1862 and soon afterwards was appointed house surgeon at the North Infirmary, a position which he held for eight years On resigning that post the governors of the hospital, in recognition of his services, elected him assistant surgeon and soon afterwards he became intern surgeon, an appointment which he held with much credit to himself and much advantage to the institution up to the time of his death He loved the North Infirmary as if it were his own private property and did much for its advancement in public esteem In the year 1880 he was appointed Professor of Surgery at the Queen's College, Cork, in succession to Dr Tanner and for some time was a member of the Council of the College He also represented Convocation on the Senate of the Royal University for a number of years He was consulting surgeon to the Mercy Hospital, was connected with several public institutions in Cork, and he enjoyed a large consulting practice Professor O Sullivan took an intense the "battle of the clubs" at Cork and he attended meetings of the health. His mature judgment was always at the disposal of his brethren. He was a man of strong views and even when they did not correspond with those of his colleagues all admired his tenacity of purpose and his sincere desire to advance the interests of the profession. His funeral was almost a public one.

Jan. 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

United Resignation of the Medical Staff of a Municipal Dispensary.

IN the Ward of Ternes at Paris there is a dispensary organised by the Municipal Council and connected with the School Board of the city (Caisse des Écoles de la Ville). At this dispensary there attend a certain number of medical men who give their services gratuitously to poor children. Each one deals with his own specialty and receives no remuneration. The mayor of the Quarter and his deputies have, however, sought to pervert this philanthropic work, which does a great service to the poor, from its proper end to that of a political and electoral engine. The authorities of the Caisse des Écoles have practically decided that children who go to any school other than the municipal schools shall be no longer allowed to receive gratuitous medical advice. This law obviously excludes all those little sufferers whose parents like to send them to schools presided over by religious orders or private teachers. Owing to this regulation, so contrary to the philanthropic feeling which prompted the 14 medical men on the staff of the dispensary to give their services gratuitously, the said staff has resigned in a body. It is necessary to insist once more upon the "cheek" (*sans-gêne*) with which public bodies in France treat the medical profession in its relations to the State, the municipalities, or the law courts. Everywhere the medical profession is treated as an underling whose duty is simply to obey the most arbitrary orders. When any salary is given it is fixed upon an absurdly low scale and for this is demanded cruelly hard work for very long hours and accompanied by heavy responsibility. When services are given gratuitously the requirements of the authorities are quite despotic and are accompanied by a complete lack of consideration. Before this last occurrence there had already been a series of petty annoyances at the Ternes Dispensary. The chief medical man sent in his resignation, whereupon a successor was appointed solely by the governors (*administrateurs*) without any reference to the opinions of the other medical men. The dispensary nurse, whose work was admirable, was threatened by the governors, anxious to manifest their political zeal, with dismissal if she sent her child to any school other than a municipal one. It must, however, be sorrowfully confessed that what renders it easy for a municipality to treat medical men in the way that they do is, as the municipality somewhat insolently answers, the fact that the number of applicants for official places exceeds the number of posts, so that no difficulty is found in filling up the vacancies caused by resignations even of unpaid posts, so great is the liking among French medical men to be an official.

Jubilee of the Society of Biology.

The Society of Biology has been celebrating with an official ceremony the fiftieth anniversary of its foundation. The Government delegates and the members of the society first assembled at the College of France where a marble tablet has been placed on the wall of the laboratory of Claude Bernard, the founder of the society. The tablet bears this inscription: "In this laboratory there worked, from 1847 to 1878, Claude Bernard, Professor of Medicine at the College of France." Orations in praise of Bernard were delivered by M. Gaston Paris, the Director of the College of France, and by Dr. d'Arsonval, who to-day occupies the chair held by the great physiologist. A grand ceremony then took place in the large Theatre of the Sorbonne where the Minister of Public Instruction was received by the officials of the society, with Professor Bouchard, the President, at their head. There were many delegates present from French and foreign societies, and among the latter were Waller of London, Blumenthal of Berlin, Héger of Brussels, and Prévost of Geneva. Speeches were made by Professor Bouchard, by the Minister of Public Instruction, and by some of the delegates. Various decorations were distributed and in the evening a banquet with more speeches concluded the festival.

Complaint against a House Surgeon.

The lay press has been making a great to-do over an alleged scandal at the Children's Hospital. A little girl is said to have died owing to the brutal treatment of a house surgeon while putting on a Sayre's jacket. A complaint has accordingly been lodged with the Tribunal, who have ordered an inquiry into the circumstances and a post-mortem examination. What really happened was as follows. The child suffered from angular spinal curvature. She was very irritable and struggled when anyone touched her. The house surgeon was ordered to put on a plastic jacket but the child tore away the bandages as they were being put on and pinched the house surgeon's arm as hard as she could. He lost patience with her and gave her a light tap on the cheek to make her keep quiet. After that she was good and the jacket was applied without any more trouble. In the evening the house surgeon, to console the child, went to see her as she lay in bed and brought her some little delicacy to eat. As ill-luck would have it, however, just at that moment the child gave one cry and died—an unfortunate event which does sometimes happen after a plaster jacket, although the occurrence is very rare. The house surgeon will certainly not be prosecuted, for all the other patients in the wards are ready to bear witness to his uniformly kind treatment of the patients and to the fact that he never ill-treated the child. But this unfortunate incident, which has been grossly misrepresented by that section of the press which is always in search of sensational copy, serves as a pretext for heaping new insults upon the medical profession.

Madness on the Stage.

One of the Paris theatres has just produced a piece in six acts under the title "In Peace." The plot deals with a matter which has for some time sadly exercised both writers and legislators; one moreover which bears directly upon the rôle of the medical man in modern society. A commercial man returning home from a long journey finds his business ruined by his son-in-law and his children to whom he had confided his affairs during his absence. Naturally annoyed at this he announces his intention of disinheriting them, so they arrange with a medical man to treat him as a lunatic and have him immured in an asylum. Four long scenes pass in the asylum and naturally enough the author makes out that many of the inmates are not mad but only there on account of family intrigues. Among them is a noble-minded priest who has recognised the impossibility of escape and has resigned himself to end his days there "in peace"—a peace which foreshadows that of the grave. The hero of the piece when he comprehends the situation falls into paroxysms of rage which naturally strengthens the opinion that he is mad. One day at the instance of some of his relations, who are disinterested, a magistrate and a medico-legal expert arrived at the asylum to make inquiries of the patient himself. But the influence of his surroundings has proved too much for his brain and he has become really mad, so that he flies at the magistrate and tries to strangle him. Henceforward he is an outcast from society and condemned to die in the prison-house. The medical man in charge of the asylum is depicted as an unscrupulous scoundrel who sticks at nothing as long as it pays him, and the attendants by his orders give morphia secretly to the morphino maniacs in order to prolong their stay in the asylum. The play has not taken the public fancy, for its real dramatic interest is *nil*, but the production has served as a peg for discussions in the press as to the exaggerated powers of medical men in such positions and to demand the carrying out of the oft-mooted, but never realised, reform of French lunacy laws.

Jan. 16th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Francesco Orsi.

BUSY as death has been in the ranks of the profession at home and abroad, it has laid a peculiarly heavy hand on the Lombard medical school. In Professor Giovanni Zoja it lately lost an anatomist of a high order and on New Year's Day, its illustrious professor of clinical medicine, Dr. Francesco Orsi, succumbed to a lingering illness. Born in 1828, he was still a student in medicine when the revolution of 1848 summoned the youth of the Alta Italia to take the field against Austria, and Orsi was among the first to enrol himself in the battalion of Lombard undergraduates. He was actively engaged in the whole campaign which, in April, 1849, closed on the field of Novara with Radetsky's decisive victory over King Carlo Alberto, and the conclusion of peace saw him once more immersed in clinical study at Pavia. In 1855 cholera was raging throughout Italy, and Orsi, still an undergraduate, repaired to the scene of its greatest prevalence, Nave, in the province of Brescia. There his fearlessness, his professional skill, and his energy did much to lighten the visitation, after which he graduated with high honours as Doctor of Medicine at Pavia. In 1859 war again broke out between Austria and Piedmont, which was this time reinforced by the Emperor Napoleon, and Orsi applied for a post on the army medical staff. His application was granted on the very day of the announcement of the Treaty of Villafranca which prematurely closed the campaign; and so indignant was he at this unexpected turn of affairs that he threw up his appointment and restricted his service to assisting Professor Porta in attending the wounded in hospital. Called to the University of Genoa to fill the chair of Clinical Medicine he did much to enhance the fame of the Ligurian school till 1866, when his Alma Mater, Pavia, secured him for her chair of Medical Pathology and Clinical Medicine. His ability in diagnosis and treatment soon gave the Lombard University a distinguished name, while his expository power, remarkable for its lucidity, succinctness, and impressiveness, brought him pupils from all parts of the kingdom. Among these may be mentioned Pietro Grocco, now head of the Tuscan school; Camillo Bozzolo, professor of clinical medicine at Turin; Achille De Giovanni, Rector Magnificus of Padua, where he is also professor of clinical medicine; and Carlo Furlanini, who holds the chair of Special Pathology in Pavia. Besides being a busy teacher and consultant he was an energetic and philanthropic citizen and filled more than one civic post in his native province with popularity and success. No less proficient in written than in spoken discourse, he published numerous treatises on difficult or debated subjects in medicine, specially valuable being his "Analisi Critica sulla Dottrina dell' Erpetismo," his monograph "Sulle Malattie del Sangue," his "Frammenti di Patologia e Terapia Generale," and his "Curiosità Chimiche." His funeral, which took place at Pavia on Jan 3rd, was inkeeping with his fame as a teacher and clinician—the "founder," in fact, of the Lombard Medical School, as he was called. The whole Senatus Academicus and the undergraduates of all the faculties, bearing the university banner draped in black, were present, as well as many former pupils holding chairs in other medical schools. Of these Professor Grocco of Florence was the spokesman of the occasion and delivered a touching discourse on the genius and virtues of the deceased. Dr. Achille Monti, professor of pathology at Pavia, followed worthily as representing the Minister of Public Instruction, Dr. Baccelli; while the syndic in a few effective periods expressed on the part of the citizens of Pavia their sense of the loss they had sustained. The ceremony concluded with the announcement of telegrams of sympathy and condolence from all parts of the Italian kingdom.

The Vatican Consultants in Medicine and Surgery.

Leo XIII. has seen and highly approved the gold medal just conferred on his chief consultants in medicine and surgery by the Roman Catholics of Novi (Liguria). The medal, of massive gold, a *chef d'œuvre* of the well known artist in that *métier* Signor P. Ferrea, presents on its obverse aspect the portraits of these distinguished functionaries, each portrait having under it the name of its subject—Joseph Lapponi and Caietanus Mazzoni. On the reverse side is given the following epigraph from the pen of an accomplished Lombard prelate:—

QUOD
E PRAESENTI DISCRIMINE
LEONEM XIII PONT. MAX.
NONAGENARIUM
CHIRURGIA ERIPUERINT
NOVENSES ALIQUOT CIVES
HONORIS CAUSA
MDCCCIC.

(Because they rescued from immediate danger by surgical intervention the Supreme Pontiff Leo XIII. in his ninetieth year some citizens of Novi have bestowed on them this medal to render them honour, 1899.) The medal gives artistic expression to the gratitude felt throughout the Roman Catholic world on the Kalends of March last when it learned that the Holy Father had emerged from his consultants' hands stronger and better than he had been for years and when within 24 hours 10,000 telegrams in that sense reached the Vatican and some 350 the private residences of Dr. Lapponi and Dr. Mazzoni. That Leo XIII. maintains his health and his energies, physical and mental, in the severest winter known in Italy for a whole generation is testimony sufficient as to the skill and care with which his consultants acquit themselves. As I write I am informed of another token of gratitude for the successful operation above referred to. This time it is conferred on Dr. Mazzoni singly by the three nephews of Leo XIII. It is a magnificent parchment, designed and illuminated by Perazzoli of Rome, and bears the following dedication: "Ludovico, Camillo, and Riccardo Pecci, gratefully honouring the distinguished master of the healing art, who in March, 1899, with skilled and assured hand, restored health and vigour to the Pontiff and peace of mind to his distressed family and to the anxious Catholic world—an arduous and splendid example of operative science which history will not fail to commemorate." The marginal ornamentation contains allegorical figures and cherubs in illustration of medicine, with various Latin mottos artistically introduced; while the armorial bearings of the Pecci and Mazzoni families sustain each other in the central space of the parchment. In the Vatican itself no fewer than three high functionaries are also under medical treatment. Of these the Cardinal Vicar (Jacobini) is somewhat better; Prince Altieri, commandant of the Pontifical Guard, is dangerously ill; while Cardinal Trombetta (in his eighty-fourth year and not expected to recover) has received from the hands of his Holiness the apostolic benediction.

Award of the Bressa Prize.

Every four years the Reale Accademia delle Scienze of Turin awards the prize of 9600 francs to the contemporary *savant* who in its judgment has deserved best of physical science or nature study during the quadriennium. Since its foundation by Signor Bressa, a distinguished ornament of the subalpine seat of learning, 11 such prizes have been awarded. This, the eleventh of the series, has just fallen to Dr. Ernst Haeckel, Professor of Zoology in the University of Jena, for "valuable contributions covering the whole field of biological science."

Jan. 14th.

Obituary.

THOMAS GREAVES WALKER, M.R.C.S. ENG., L.S.A.

MR. THOMAS GREAVES WALKER died at his residence, Colston's-parade, Bristol, on Jan. 8th from pneumonia, after a short illness. Mr. Walker was educated at the London Hospital and qualified as L.S.A. and M.R.C.S. Eng. in 1885 and 1889 respectively. The deceased, who was only 39 years of age, had been in practice in Bristol for 10 years. He was extremely popular not only with his patients but also amongst the members of the medical profession. Mr. Walker was medical adviser to the local branch of the Society for the Prevention of Cruelty to Children and took great interest in the work. Much sympathy is felt in Bristol for his widow and children.

AMBULANCE WORK IN THE FIELD.—Surgeon-General G. J. H. Evatt, principal medical officer of the Western District, gave an interesting lecture at the headquarters of the local volunteers in Plymouth on Jan. 10th, the subject being "The Organisation and Working of the Army Medical Service in the Field." Surgeon General Evatt alluded to the fact that in the Western District, stretching from Land's End to Gloucester, there were only two army surgeons left—himself and another. Civilian surgeons were coming forward to assist and a militia medical corps was being organised to take the place of the regulars who were going abroad.

University of Oxford.—The following candidates at the recent examinations were successful.—

Final Examination for the M B Degree.

Pass List—A. C. Goodwin, B A., Keble, F. P. T Hilliard, B A, Magdalen, F. O Stoehr, B A, Trinity; and J A Willett, B A, University.

Pathology alone—E D Bond, B.A., Keble; J D Rolleston, B A, B N.C., J E H Sawyer, B A, and W. V. Shaw, Christ Church, F. J Stevens, M A., Exeter, A. E Thomas, B A, Merton, and R. Warren, B A, New.

First Examination for the M B Degree.

1 *Organic Chemistry*—G D. Allen, non collegiate, G Hely-Hutchinson Almond, Hertford, L T Burra University, E Burstal, Trinity, D Davidson, Brasenose, H. R Dean, New; J Freeman, University; R C Jewesbury, Christ Church; H A. Philpot, New, E Whitley, Trinity; and A R Wilson, Wadham

2 *Materia Medica and Pharmacy*—T E. C Cole, Christ Church, W. L. M Day and A. C. Le Rossignol, Exeter College, and A. J. Wigmore, non collegiate

3 *Human Anatomy and Human Physiology*—E L. Farncombe, St. John's; A. H. Hogarth, Christ Church; C M H Howell, Trinity, L D Neve, Merton, and P. F Tinne and *H. M Turnbull, Magdalen.

* Offers Human Anatomy only, being exempt from examination in Human Physiology.

Examining Board in England by the Royal Colleges of Physicians and Surgeons—The following gentlemen passed the Second Examination of the Board at the January quarterly meeting of the Examiners in the subjects indicated:—

Anatomy and Physiology—Joseph Baird Albury, St. Mary's Hospital, Edward Whyte Alment, St. Bartholomew's Hospital, Oliver Francis Haynes Atkey and Harold Balme, King's College, London; Francis Barton, University College, Liverpool, Algernon James Beadel, Guy's Hospital, Stanley Bennett, Cambridge University and St Bartholomew's Hospital, Charles Reginald Bradley, St George's Hospital, George Russell Haines Chell, Mason College, Birmingham; George Martin Clowes, London Hospital; Robert Harry Lucas Cordner, St George's Hospital, Thomas Reginald Couldry, St. Bartholomew's Hospital; Harold Juler Cundell, St. Mary's Hospital; Harold Stewart Cassan Darbyshire, University College, Sheffield, and St Thomas's Hospital, Edward David Davis, University College of South Wales, Cardiff, Harold Benjamin Day, Kings College, London, William Frank Lydston Day, Cambridge University, Percy Toplis Drabble, University College, Sheffield; Raby Montague Grogono, London Hospital, Charles Walter Cowell Harvey, St Bartholomew's Hospital, Philip Arthur Hendley, King's College, London, Vernon Hetherington, St. George's Hospital, James Howard, Owens College Manchester, Ernest Charles Hodgson, and Guy Hughes, St Bartholomew's Hospital, William Ibbotson, University College, Sheffield, Reginald Lewis Jones, Cambridge University and Middlesex Hospital, Ernest Henry Kenderdine, Mason College, Birmingham; Charles Samuel Kingston, St Bartholomew's Hospital, John Lloyd Lewis, London Hospital, John Daniel Stuart Lloyd, Mason College, Birmingham, Allen Douglas Low, Nelson Low, Owen Leonard Lowsley, William Terrance McCowen, and Edward Henry Milner-Moore, St. Mary's Hospital; Lionel Henry Moiser, Yorkshire College, Leeds, and Guy's Hospital, Charles Molteno Murray, Cambridge University and Guy's Hospital, John Patten Nettell, London Hospital, Edward Newton, Cambridge University and St George's Hospital, George Blake Norman, Cambridge University and St. Mary's Hospital, Loraine Orton, Cambridge University and St Bartholomew's Hospital, Thomas Hamilton Ollerhead, Arthur Frederick Pilkington, and Ernest Aubrey Price, St. Mary's Hospital, Frederick Paine, Middlesex Hospital, John Douglas Pearson, Guy's Hospital, James Houston Porter, London Hospital, George Herbert Richard and Percy John Robbins, St Mary's Hospital, Edmund Arthur Roberts and John Latham Rushton, Kings College, London, Frederic Emilius Roberts, St. George's Hospital, Robert Poole Sephton, Cambridge University and Owens College, Manchester, Edward Bertram Smith, St Bartholomew's Hospital, Frederick Morton Vincent Smith, Guy's Hospital and Mr Cookes' School of Anatomy and Physiology, Daniel Jenkins Thomas, University College of South Wales, Cardiff, John Haydon Timothy, King's College, London; Francis John Turner, Guy's Hospital, Hugh Waddell, Queen's College, Belfast, Henry James Davey Walker, London Hospital, and Charles Murray Woods, Charing cross Hospital.

Anatomy only—Joseph Wilding, St. Bartholomew's Hospital

Physiology only—James Ewing, Yorkshire College, Leeds, and Graham Lionel John Wilson, St George's Hospital

44 gentlemen were referred in both subjects and one in Physiology only.

Plymouth Royal Eye Infirmary.—The annual meeting of this institution was held on Jan 10th. The medical report showed that 1890 patients had received treatment during 1899; of these, 1560 were either cured or relieved, the remainder being still under treatment. There had been 255 in-patients admitted, the daily average number being 14 The treasurer stated that the receipts amounted to £2378 and the expenditure to £2214. It is hoped that the new infirmary at Mutley, on which £13,418 has been expended, will be ready for occupation early in March.

Royal College of Surgeons in Ireland.—Mr. Arthur Chance has been elected a member of the council of the College.

A Medical Magistrate.—Sir John Williams, Bart, M.D., F.R C.P., Lond, has been placed on the Commission of the Peace for the county of Carmarthen.

Barry Accident Hospital.—At the meeting of the *Hospital Committee of the Barry District Council* it was decided to take over the Accident Hospital and to conduct the building in future at the expense of the rates. The medical staff will continue to give their services gratuitously.

Royal United Hospital, Bath.—The annual meeting of the Royal United Hospital Working Association was held on Jan. 20th. The report showed that this useful society had supplied 1016 gifts in clothing to the hospital, representing a value of £200.

Presentation to a Medical Man.—Mr. Andrew McMillan, M.D. Aberd, of Stanley, Perth, on his recent retirement from active practice, was on Jan. 11th the recipient of a public testimonial as a token of the esteem in which he has been held by the community after a professional career of 37 years. The presentation was made by a deputation of friends who waited upon Dr. McMillan at his residence, and consisted of a solid silver salver suitably inscribed, an aneroid barometer and thermometer, and a purse containing 60 sovereigns.

Drainage of Chard.—At the last meeting of the Chard Town Council a letter was read from the solicitor of the Lord of the Manor, stating that they were about to commence proceedings against the council for polluting the Chard reservoir with town sewage and that a writ would be issued forthwith. After some discussion the council decided to adopt a scheme of drainage recommended by Mr. C. T. Walrond, C E., of London, estimated to cost £8000, and the town clerk was instructed to ask for a stay of the threatened legal proceedings.

Freemasonry.—*Rahere Lodge*, No. 2546.—An ordinary meeting of the Rahere Lodge, No. 2546, was held at Frascati's Restaurant on Jan. 9th, when Bros. Worth and Slater were raised to the degree of Master Mason. The death of Bro. Bill was announced and a vote of sympathy with his relations was unanimously passed. The following grants were confirmed: (1) £21 to the British Medical Benevolent Fund; (2) £50 to the Soldiers' and Sailors' Families Association; (3) £25 to the Depot Mobilisation Relief Fund for orphans and widows of members of the Royal Army Medical Corps; (4) £25 to the Orphans and Widows of Officers' Fund; (5) £1 1s. to "Our Brothers' Bed" at the Home for the Dying; and (6) £10 10s. to each of the three masonic charities to be placed on the list of the respective stewards for the festivals. After the meeting 20 brethren dined together.

Society for the Relief of Widows and Orphans of Medical Men.—A quarterly court of this society was held on Jan 10th, Mr. Christopher Heath, Vice-President, being in the chair Two new members were elected and the deaths of Sir James Paget, President, and Mr. Grimson, a director, were reported. Mr. Christopher Heath from the chair proposed the following motion: "The quarterly court of directors of the Society for the Relief of Widows and Orphans of Medical Men desires to record its great regret at the death of Sir James Paget, Bart, the President of the society, who has for many years taken the greatest interest in the society's welfare and until recently has regularly taken the chair at the meetings of the court." There were no fresh applications for grants and the death of a widow was announced who had received since January, 1875, £1333 10s from the funds. It was resolved that £1205 10s be distributed among the 48 widows, 11 orphans, and the six recipients from the Copeland Fund. The Christmas present, £531, had been given on Dec. 18th. The expenses of the quarter amounted to £74 14s. 6d. The nomination of a President was postponed to the April court.

BRISTOL MEDICAL CHARITIES—The employés of Messrs W. D. and H O Wills during 1899 voluntarily collected £364, which has been divided amongst the different medical charities of Bristol

ROYAL VICTORIA HOMES, BRENTRY.—At the meeting of the Newport (Mon) Corporation held on Jan 9th it was decided to contribute £1000 to the funds of the Royal Victoria Homes, Brentry, in consideration of having seven beds reserved for a period of 25 years

HEALTH OF CARDIFF.—Dr. E. Walford, the medical officer of health of Cardiff, states that during 1899 there were 5309 births and 2857 deaths registered, equal to a rate of 28 5 and 15·3 per 1000 respectively The death rate in 1898 was 14 8 per 1000, the lowest rate since 1845

HOSPITAL SUNDAY IN BIRMINGHAM.—A meeting, presided over by the Lord Mayor, was held on Jan 4th at the Council House, Birmingham, to receive the report and balance sheet of the years collections and to present a cheque to a deputation from the Queen's Hospital, on behalf of which institution the collections were made. The report stated that the day appointed was Oct 29th and, with one or two exceptions, all the collections at places of worship were taken on that day. The number of places of worship at which collections were made was 276, thus making, with five contributions from personal or anonymous sources, 281 returns, as compared with 280 in 1898 The gross receipts amounted to £5304, as compared with £5246 in 1898, when the collection was for the General Hospital, and £5267 in 1896, the last occasion when the Queen's Hospital benefited It was, indeed, the largest collection that had been raised for 21 years, namely, since 1878, when the collection exceeded £6000 The Lord Mayor, after the adoption of the report and balance sheet, handed to Sir James Sawyer, on behalf of the Queen's Hospital, a cheque for £5059 2s 7d

---

THE PRESERVATIVES AND COLOURING MATTERS IN FOOD

EVIDENCE BEFORE THE DEPARTMENTAL COMMITTEE

MONDAY, JAN 15TH

THE Committee appointed by the President of the Local Government Board to inquire into the question of preservatives and colouring matters in food resumed its sittings after the holidays to-day, when it examined three witnesses. Sir HERBERT MAXWELL, M P , Chairman of the Committee, occupied the chair

Mr SAMUEL RIDEAL, Doctor of Science and Fellow of the Institute of Chemistry, was the first witness and in answer to the chairman he explained that his views with regard to preservatives in food had been set out in a paper by Mr A G R Foulerton and himself published in *Public Health* for May 1899 He and Mr Foulerton had engaged in a number of experiments to ascertain the actual amounts of boric acid and borax on the one hand and formaldehyde on the other, which were necessary for preserving purposes in milk As the result of these experiments they came to the conclusion that one part of formaldehyde in 50 000 was sufficient to preserve milk, even in warm weather, for 24 hours, and that one in 2000 of a mixture of boric acid and borax was sufficient for the same purpose Having arrived at these conclusions they then attempted to ascertain whether these quantities had any effect upon the digestibility of food. The conclusion they came to was that the effect of these quantities of preservatives was inappreciable upon the digestibility of food even after contact for 24 hours There was a certain slight retarding effect noted, but no inhibiting effect These experiments were made *in vitro*, but he had performed experiments upon animals to supplement them The latter showed that the quantities of formaldehyde had no effect upon the nutrition of cats or guinea pigs or rabbits The cats experimented with were three months old and the guinea pigs and rabbits were adults He had tried with kittens of three or four weeks at first, but he found it difficult to feed them by hand for the natural milk of a cat contained a very much larger quantity of albumen than the milk of a cow Since making the experiments he had read Dr H F Annett's paper in THE LANCET,[1] and he desired to point out that Dr Annett gave no information as to the quantity of milk consumed by the kittens

The CHAIRMAN said that Dr Annett had told the Committee that he gave the kittens as much as they would take.

Mr RIDEAL, continuing his evidence, said that he did not consider the quantities which he had given to be the maximum that could be taken with safety The question really resolved itself into the susceptibility of the individual. Cases were recorded of 20 grains of boric acid having produced rash symptoms but that would correspond to a very large quantity of milk containing one in 2000 of boric mixture He did not think that anyone should be allowed to put an unlimited amount of preservative into milk He advocated a limitation of the amount and a declaration to the consumer of its presence He considered that the quantities he had mentioned were suitable quantities for preserving purposes, and if they were declared they could be used by the majority of people with impunity In the case of invalids and young children, however, the milk should be altogether free from preservatives Even smaller quantities than he had mentioned might be used if they were added at the time when the milk was taken from the cow.

Professor THORPE then examined the witness as to certain tables which he had prepared, the object of the examination being to show that the quantities mentioned would have little preserving effect upon the milk —Mr RIDEAL, however, insisted that these quantities were sufficient for preserving purposes for 24 hours even in warm weather.

In reply to Dr BULSTRODE, witness said that he was not prepared with evidence to show that larger quantities would have effects prejudicial to health

Mr. CHARLES CASSAL, Public Analyst for Kensington, St. George's Hanover square, Battersea, and other districts, was the second witness He expressed the opinion that the position of the public analyst in regard to preservatives and colouring matters in food should be clearly defined by the Legislature or by an authority delegated by the Legislature The public analyst, he said, must have a definition of what constitutes adulteration for the purposes of the Sale of Food and Drugs Acts, and he thought that the legislature should see that the necessary experiments were carried out His view was that the purchaser was entitled to a clear and explicit declaration of the nature of the article which he received In the present state of things the local authorities found great uncertainty and expense in connexion with proceedings If it were held that it was necessary to use chemical preservatives then the nature, amount, and effect of the preservatives employed should be disclosed to the purchaser He was of opinion that it was quite possible to carry on the milk supply of a large community like that of London without recourse to chemical preservatives For instance, the Aylesbury Dairy Company supplied an enormous district and it never used preservatives either in milk, cream, or butter, and other large firms were in the same position He had it from people engaged in the milk trade that it was not only possible but right and proper, that the milk supply of a large community should be free from chemical preservatives What they did was to adopt cold treatment which was found to work quite satisfactorily If it were contended that small vendors had not the means for this treatment then he replied that they should not go into the business without proper equipment for it. His view of these preservatives was that they were foreign ingredients and that their presence constituted adulteration quite apart from the question of their injuriousness He advocated the prohibition of preservatives, and failing prohibition the disclosure of their presence to the purchaser At different times he had examined samples of milk supplied to large institutions and hospitals in London and although he had not in any of these cases determined the proportions he had in a number of instances found boric preparations present in the milk He had found salicylic acid in wines—in small quantities in foreign wine and in large quantities in so-called British wine In orange wine he had found 26·6 grains per gallon, in wine called British sherry 11·50 grains, and in black currant wine four grains With regard to formaldehyde he was of opinion that its use was considerably on the increase. Experiments made by himself and others went to show that formaldehyde even in dilute solutions affected some of the constituents of food material in such a way as to make them practically insoluble and incapable of digestion. He had not made any determination of quantities of formaldehyde in samples of milk submitted to him because at present there was no satisfactory process of estimation, though no doubt in time one would be devised With regard to colouring, there was some colouring which might be considered legitimate but others, again were fraudulent and ought to be prohibited. For instance, he would stop the colouring of peas with sulphate of copper

By Dr BULSTRODE: He opposed the use of any preservative other than salt and he recommended the use of cold storage as the best means of carrying on trade.

Mr DE HAILES, analyst to the Dairy Trade Protection Society, the third witness examined gave to the committee an account of the means by which milk was brought from distant places to London and insisted that preservatives must be used As for cold storage he said that many farmers were without the means for adopting it. He was aware, he said, that some milkmen make a great point about not using preservatives, but they were careful to get their supplies from farms within a short distance of London He would not like to say that it was impossible to supply milk to London for a greater distance than 40 miles without preservatives, but he would say that the milk trade as at present carried on, could not be carried on without preservatives He saw great practical objection to vendors being required to make a declaration to each purchaser of the presence of preservatives, especially in view of the manner in which the Sale of Food and Drugs Acts was administered, although he should have no objection to a notice being exhibited in the shop saying that the milk sold there was preserved. He also saw objection to a declaration in each case when butter with a preservative was sold.

The Committee then adjourned

TUESDAY, JAN. 16TH

The Committee met again to-day with Sir HERBERT MAXWELL in the chair and proceeded with the examination of witnesses

Mr ALEXANDER G. R. FOULERTON, bacteriologist to the Middlesex Hospital examined by the CHAIRMAN, said that in his opinion preservatives in milk were necessary, especially in the case of small retailers who had to supply the poor and could not get rid of surplus milk in the same way as large companies. He was of opinion that the amount of such preservatives as boric acid and formic aldehyde present in milk was absolutely harmless to the ordinary individual who took a small quantity of milk on the other hand he thought that to an invalid or a child the amount might be and probably in some cases would be decidedly hurtful The boric acid in the case of an invalid or a child was capable of producing toxic symptoms, but he did not think that formic aldehyde would produce these symptoms, though it might make the milk less digestible. He thought that the public ought not to be allowed to buy preserved milk without knowing it in order that invalids and children might be protected The amounts which he should consider safe for the average individual were, supposing that about one pint of milk were taken per day, 1 in 2000 of boracic acid and about 1 in 50,000 of formic aldehyde His idea about preservatives was that they should be used to keep good milk fresh and not to keep stale milk. Under the present system it was almost impossible for poor people in London to get good milk without the use of preservatives. The system might be modified but that would involve doing away with the small retailer. He was aware that in some foreign countries the use of preservatives was prohibited, but he saw great difficulties in the case of large communities whose milk-supply was brought from a distance. He did not for a moment contend that the interests of the small trader were to be placed before the interests of the public health. He confessed that the disappearance of the small trader would be an excellent thing for the public health, but he did not know whether it could be done. He advocated a declaration of the presence of preservatives in milk as a safeguard and speaking generally, he was in favour of declaration rather than prohibition.

---

[1] THE LANCET, Nov 11th, 1899, p 1282.

In examination by Professor Thorpe the witness took exception to the idea that the experiments of himself and Mr. Rideal showed the amounts of preservatives used to have had practically no effect in preventing the change in milk. In his own experience, he said, he had kept overnight milk with one in 50,000 of formic aldehyde and found it perfectly sweet next morning, while similar milk without the formic aldehyde became tainted. Explaining his position further, Mr. Foulerton said he did not regard the question merely from the point of view of the small trader, but from the public health point of view. The small trader might sell a perfectly good milk and it might be taken into a dirty, little room with half a dozen people living in it, and surely it was to the advantage of the public health that the milk should be kept in a good condition as it would be by the addition of a preservative. It might be said that these were conditions in which milk should not be kept, but, as a matter of fact, it was kept in those conditions in many of the poor districts of London. Of course, if the conditions were removed the necessity for a preservative would disappear.

By Dr. Bulstrode: He was not aware whether 91 per cent. of the milk-supply of Birmingham was free from preservative, but if such were the case he supposed the conditions of that city must be different from those of London. He could not conceive that milk free from preservative could be kept good in a crowded house for 24 hours during the hot weather. If declaration were found to be impracticable then he should advise prohibition.

By Dr. Tunnicliffe: Before determining the preservatives which should be allowed there would require to be very considerable further inquiry and no doubt the list would require to be altered from time to time as circumstances demanded.

Mr. Harald Faber, Fellow of the Chemical Society and Commissioner in this country for the Danish Government, was the next witness, and, in reply to the chairman he said that his duties were to watch over the interests of Danish agricultural produce coming to this country, to keep his Government informed on various matters, to see that no misrepresentations took place, to advise as to improved methods of manufacture or sale, and to find new outlets for trade. He had in the discharge of these duties given attention to the subject of preservatives in food, and his opinion was that preservatives in food ought not to be used unless when declared. These preservatives were chemicals, and the people who used them, not being generally chemists, were unable to judge of the quality of the articles they used and they were also ignorant of their effects. The idea of preservatives was to prevent the food decomposing, but in the course of digestion these very articles of food were intended to be decomposed, and therefore the preservatives were liable to prevent proper digestion. In Denmark salicylic acid, boric acid, and certain mineral salts were prohibited altogether. Saccharin in beer and wine was not allowed unless declared on the label. There was an expression of opinion from the Royal Board of Health, dated October, 1895, that the use of boric acid or borax in food to a certain extent, one gramme daily, was considered by them to be injurious to health. No inconvenience was felt in the dairy trade of Denmark in consequence of the prohibition of preservatives. In butter and margarine no other preservative than common salt was allowed. The town of Copenhagen had about 450,000 inhabitants and they consumed a larger quantity of milk per head than the people of this country, and though the milk came from very distant places to the town the supply was adequate and in every respect satisfactory. One large company sterilised every drop of milk it sold. It was sterilised in bulk and then put in sterilised bottles and sold in that way. The heat applied was at least 85° centigrade. Previously to the prohibition of preservatives attempts had been made in Denmark to introduce them, but the dairy farmers did not take to the preservatives and the attempts never succeeded. In the case of butter some of it was exported without salt but most of it was salted to some extent, usually to the extent of about 1 per cent. The butter so salted kept good for at least three weeks, even in hot weather—indeed, long enough for the purposes of the trade. For himself, he did not believe that the use of preservatives improved the keeping of butter to any great extent; the thing to see to was that the butter was properly made. Danish butter was almost exclusively made from sterilised milk. Under an Act recently passed milk could only be sent out for food for cattle which had been Pasteurised to at least 85° C. or which had come from a cow which had stood the tuberculin test. This measure was designed to prevent the spread of tuberculosis in cattle.

By Professor Thorpe: If the Pasteurisation was carefully done it did not in the least affect the flavour of the milk. He had been present at an experiment when the milk was heated to over 90° centigrade, and experts were unable to distinguish between this milk and milk which had not been heated. There had been no difficulty in Denmark in persuading people to adopt Pasteurised milk for consumption; indeed, it was a common thing for them to buy the raw milk and heat it themselves. Raw milk was regarded by a large proportion of the people of Denmark as a thing to be avoided. Witness repudiated altogether the allegation that in recent years there had been some deterioration in the keeping qualities of Danish butter. He insisted that Pasteurisation of the milk had had nothing but beneficial effects upon the butter. For years and years butter from Pasteurised milk had taken the prizes at the dairy shows.

By Dr. Bulstrode: More than half the foreign butter imported into this country came from Denmark and consequently had no preservative beyond 1 per cent. of salt.

Mr. A. Gilbey of Messrs. W. and A. Gilbey, wine-merchants, the third witness examined, gave evidence as to the presence of preservatives in wines imported into this country. He stated that salicylic acid is very little used and indeed that it is unnecessary to use it in wines of the strength of those which are imported into England. In the case of his firm if they had reason to suspect its use in a particular country or district they made it a condition in their contracts that the wine should be free from it. His firm were not aware whether salicylic acid was injurious to health, but there was a prejudice against it in the public mind and for that reason they insisted on its absence.

The Committee then adjourned.

WEDNESDAY, JAN. 17TH.

The Committee met again to-day, Sir Herbert Maxwell presiding, and proceeded with the examination of witnesses.

Mr. T. Carrington Smith, dairy farmer in Staffordshire, chairman of the Dairy Products Committee of the Central Chamber of Agriculture, along with Professor James Long, Cheshunt, gave evidence on behalf of the Central Chamber of Agriculture.—Mr. Smith informed the committee that the Chamber had passed a resolution declaring that it was opposed to the employment of preservatives and colouring matters in articles of dairy produce, whether British or imported, and appointing representatives to urge before this Committee that as preservatives and colouring matters were believed to be injurious to the health of invalids and children their use should be prohibited. Speaking from his own experience he said that the prohibition of preservatives would not interfere with the daily supply of fresh milk to large communities. His farm was over 120 miles from London, and during the year from Michaelmas, 1898, to Michaelmas, 1899, he sent to London the whole of his milk with the exception of the Sunday morning milk and though he used no preservative there had not been the slightest suspicion of any sourness, there had been no complaint made to him by the consignees, and he had never lost a single pint of milk. The morning milk reached Willesden at about 11.15 A.M. and the evening milk late overnight. Mr. Smith explained that he cooled the milk by passing it over a series of tubes through which cold water ran. Although the word "refrigerator" was used to describe the apparatus, the temperature did not at all approach the freezing point. In his opinion a good water-supply was a *sine quâ non* for dairying purposes and all that was necessary for this cooling process was a good supply of water. Mr. Smith said that he and his farmer friends thought that the consignees in the large towns might do more than they do at present to keep the milk cool after they have received it, and not only so, but also that the railway companies might arrange to have a better temperature in their milk vans. His idea of a good temperature for milk was 60° Fahrenheit. With regard to colouring, Mr. Smith said that when he was engaged in the cheese trade he used annatto to make a highly-coloured cheese, which had great favour in certain industrial centres in the North of England. Nobody, however, was deceived, for the material was well known to be artificially coloured. As a representative of the Central Chamber of Agriculture he advocated the prohibition of both preservatives and colouring matters, though personally he did not think the two things stood upon the same platform.

By Professor Thorpe: The two things that he looked to to keep milk in good condition were cleanliness and coolness, both of which were within the reach of the ordinary farmer, and he submitted that if he were able last summer in the exceptionally hot weather to send his milk every day to London without recourse to preservatives, the milk trade generally could be carried on without them.

By Dr. Tunnicliffe: He did not believe that a legal prohibition of preservatives would have more than a temporary effect upon the price of milk.

Professor James Long in the course of his evidence said that he was distinctly of opinion that dairy traffic generally, and the milk traffic in particular, could be carried on without the use of preservatives. Simply by taking proper precautions an ample and satisfactory supply of milk could be maintained in large communities. If the use of preservatives were prohibited the farmers would have no difficulty in supplying the milk and the buyers in the large cities would no doubt protect themselves by constructing cool chambers for the reception of the milk. He thought that there was a great deal to be done in the way of cleaning the milk by separation, for milk not cleaned could not be expected to keep. Professor Long exhibited to the Committee a quantity of slimy matter which had been taken from six gallons of milk by an ordinary sieving process. He considered that purchasers were entitled to be protected from the introduction unknown to them of what might be harmful drugs into a common article of food like milk, and he suspected that a good deal of injury was being done by the increasing use of these preservatives. He also objected to the use of colouring matters and said that the high colour sometimes desired in dairy products could be attained by a selection of particular breeds of cattle.

Mr. Walter William Fisher, President of the Society of Public Analysts and public analyst for the counties of Oxford, Berks, and Bucks, the city of Oxford, and the borough of Banbury, said that he and Dr. Thomas Stevenson had been asked by the Society of Public Analysts to give evidence. He could not say that he had the authority of the society to represent its views, because the society as a body had not come to any definite conclusion upon some of the important matters before the Committee. With the assistance, however, of members of the society he had prepared a statement of the facts of the case with regard to the use of preservatives and colouring matters in food and he would hand it in for the information of the Committee. His opinion was that the free use of preservatives should not be legalised, that indeed some effort should be made to limit their use. There could be no doubt that the use of preservatives had grown very considerably in recent years and unless it was checked in some way it would further extend and it would become very difficult if not impossible for people to get articles of food free from preservatives. His opinion was that in some cases preservatives should be prohibited altogether and in others their presence should be declared. He would prohibit preservatives in new milk when it was sold as new milk, and when milk was not sold as new milk he would recommend that there should be a maximum limit for preservatives prescribed. He would not dogmatise about formalin, though he was rather suspicious about this preservative because he had noticed that when milks were preserved with it it was very difficult to dissolve the curd in hydrochloric acid. He could not say of his own knowledge what the effect of small doses of formalin would be upon the human organism. The statement of the facts of the case which he had submitted to the Committee showed that there was great variation in practice as to the quantity of preservative added to milk. The people who sold the preservative stated on the package that it was absolutely harmless and the milkman had no special knowledge which enabled him to test the accuracy of the statement, and therefore it appeared to him it was desirable to fix a superior limit. He admitted that at present it was difficult often to convince magistrates, but if a limit were fixed it would be something to which public analysts could appeal. If this Committee got together sufficient evidence to show that formaldehyde was undesirable in food, then the fact that it was difficult to determine formaldehyde quantitatively would be a good argument for its prohibition. He considered that new cream should be treated like new milk, and that in the case of fresh meats and fish if they were sold as fresh they should be without preservatives. As to salted and preserved meats and fish, if a limit were fixed it should be a low one. He was not prepared to say that preservatives should not be allowed in such articles as ham and bacon. He had very little information about colouring matters, though he was aware that Congo red was used to colour meat, that bloaters were coloured with a little red earth, and that saltpetre was also used to improve the colour of meat. He considered it objectionable to colour peas with copper.

Dr. THOMAS STEVENSON, President of the Institute of Chemistry, Adviser to the Home Office and Public Analyst, said he objected to the use of preservatives in milk because of the risk to invalids and infants. He attached great importance to the experiments of Dr. Annett; he considered them extremely valuable, and he hoped they would be continued upon a larger scale. He was of opinion that the indiscriminate use of preservatives was attended with very great danger, especially to people suffering from certain complaints. As for salicylic acid it had very considerable effect upon some people, though upon others it had very little. The fact that it had little effect upon some was no proof that it was non-injurious. In connexion with lead poisoning it was found that many people drank the lead-polluted water and that only a fraction of them suffered. One objection to boric acid in milk was that it enabled the milkman to pass off as fresh milk that was really stale. On account of the odour it gave out only small quantities of formaldehyde could be used without detection, but even small quantities must harden the food very much, and therefore he objected to it altogether in such an article as milk. He thought it would be well to prohibit preservatives, although upon health grounds he saw no considerable objection to the use of boric acid in very minute quantities in butter and probably in a few other articles. His strongest objection was to the use of preservatives in milk. In regard to colouring matters there had been many changes in recent years and especially in connexion with confectionery, and they had been upon the whole advantageous. He would prohibit the use of copper to colour peas because of the danger to health and because he considered it unnecessary.

The Committee then adjourned.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, King William-street, Strand, London.
Aids to Materia Medica. Part III. By William Murrell, M.D., F.R.C.P. 1900. Price 2s. 6d.

BALE, J., SONS, AND DANIELSSON, Great Titchfield-street, London, W.
Darwin and Darwinism, Pure and Mixed: A Criticism with some Suggestions. By P. Y. Alexander, M.A., LL.D. 1899. Price 7s. 6d. net.

BLACKIE AND SON, Old Bailey, London.
An Introduction to Analytical Chemistry. By G. G. Henderson, D.Sc., F.I.C., and M. A. Parker, B.Sc. 1899. Price 5s.
The Principles and Practice of Modern House Construction. Edited by G. L. Sutcliffe. Illustrated. Divisional Vol. vi.

BOYLE, R., AND SON, Holborn Viaduct, London.
The Boyle System of Ventilation.

CHURCHILL, J. & A., Great Marlborough-street, London.
Diet and Food. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P. Second edition. Illustrated. 1900. Price 2s.

F. A. DAVIS COMPANY, Philadelphia.
The Surgical Diseases of the Genito-Urinary Tract, Venereal and Sexual Diseases. By G. F. Lydston, M.D. 1899.

GLAISHER, H. J., Wigmore-street, London.
On Granular Kidney and Physiological Albuminuria. Being the Lettsomian Lectures. By Sam. West, M.A., M.D. Oxon., F.R.C.P. Lond. Price 7s 6d. net

GRESHAM PUBLISHING COMPANY, Farringdon-avenue, London.
The Principles and Practice of Modern House Construction. Edited by G. Lister Sutcliffe. Illustrated. Vols. i. and ii. 1899. Price 50s.

HADDEN, BEST, AND CO., West Harding-street, Fetter-lane, London.
Local Government Law and Legislation for the Year ending 30th September, 1899. Edited by W. H. Dumsday, Barrister-at-Law. 1899.

The Races of Man: An Outline of Anthropology and Ethnography. By J. Deniker, Sc.D., Paris. Illustrated. 1900. Price 6s.

SMITH, ELDER, AND CO., Waterloo-place, London.
Transactions of the Pathological Society of London. Vol l. 1899.

SWAN SONNENSCHEIN AND CO., London.
Muscle, Brain, and Diet: A Plea for Simpler Foods. By E. H. Miles M.A. Camb. 1900. Price 3s. 6d.

The British Almanac and Family Cyclopædia for 1900, 73rd year of issue (Chas. Letts and Co., Royal Exchange, London, E.C.), price 1s.—Mental Nursing, by William Harding, M.D. Edin., M.R.C.P. Lond. (The Scientific Press, Southampton-street, Strand, London, 1899), price 1s.—The Problem of South African Unity, by W. B. Worsfold, 1900 (Geo. Allen, Charing-cross-road, London), price 6d. net.—Home Nursing of Sick Children, by J. D. E. Mortimer, M.B., F.R.C.S., L.S.A., 1899 (The Scientific Press, London), price 1s.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARLOW, JOHN, M.D., F.R.C.S., has been appointed Additional Examiner in Clinical Surgery in the University of Edinburgh.

BRAMWELL, EDWIN, M.B. Edin., has been promoted Senior House Physician to the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, vice J. S. Collier.

BROOK, WM. F., F.R.C.S. Eng., of St. Helen's-road, Swansea, has been appointed by the Secretary of State for the Home Department to act as a Medical Referee under the Workmen's Compensation Act, 1897, for the Neath Division of County Court Circuit, No. 31.

BUZZARD, E. FARQUHAR, M.A., M.D. Oxon., M.R.C.P., has been appointed Junior House Physician to the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, vice E. Bramwell.

CLEGG, J., M.B. Lond., M.R.C.S., has been appointed an Honorary Medical Officer to the Urmston Cottage Hospital.

COLES, A. C., M.D. Edin., has been re-appointed Medical Officer of Health by the Denton District Council.

DINGWALL, A. M.B., C.M. Aberd., has been appointed Medical Officer for the Kinsham and Pembridge Sanitary District of the Kington Union.

HAYSON, E. R., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer for the Eighth Sanitary District of the Southmolton Union.

JENKINS, HERBERT STANLEY, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Bristol Royal Hospital for Sick Women and Children, vice Wyndham Milligan, resigned.

LEADER, HAROLD, M.B., has been appointed House Physician to the East London Hospital for Children and Dispensary for Women, Shadwell, London, vice Percy S. Blaker, resigned.

MACDONALD, D., M.B., C.M. Glasg., has been appointed Local Medical Officer for Glenmoriston by the Aird District Committee.

MACDONALD, R. C., M.B. Aberd., L.R.C.P., L.R.C.S. Edin., L.F. .S. Glasg., has been appointed Local Medical Officer for the Boleskine portion of the parish of Boleskine and Abertarff.

Morris, C. D., L.R.C.P. Lond., M.R.C.S., has been re-appointed District Medical Officer by the Sunbury Urban District Council.

Quayle, Edwin, L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Medical Officer to the Urmston Cottage Hospital.

Saunders, E. Simes, M.D., C.M. Aberd., has been appointed Medical Officer to the Dispensary, Royal Albert Hospital, Devonport, vice Alonzo Rider, resigned.

Scatliff, A. W., L.R.C.P., L.R.C.S. Edin., D.P.H. Eng., has been re-appointed Medical Officer by the Margate Town Council.

Slader, G. W. B., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Gainsborough Rural District Council.

Thomas, Jabez, F.R.C.S. Eng., Ty Cerrig, Swansea, has been appointed by the Secretary of State for the Home Department to act as a Medical Referee under the Workmen's Compensation Act, 1897, for the Neath Division of County Court Circuit No. 31.

Turner, F. S., L.R.C.P., M.R.C.S., has been re-appointed Medical Officer for Penn and Coleshill of the Amersham Union.

Wilson, W. Cheyne, M.D., C.M. Edin., has been appointed by the Admiralty to give instruction in the Roentgen rays at the Naval Hospital, Plymouth, to such naval medical officers as may be detailed to go through the course.

Wood, W. Dyson, L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Henley District Council.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.

Bolton Infirmary and Dispensary.—Junior House Surgeon for twelve months. Salary £80 per annum, with apartments, board, and attendance.

Brixton Dispensary, Water-lane, Brixton.—Resident Medical Officer for two years, unmarried. Salary £150, with furnished apartments, attendance, coals, and gas.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—House Surgeon. Salary at the rate of £50 per annum, with board and residence in the hospital.

Chelsea Hospital for Women, Fulham-road, S.W.—Clinical Assistant. Tenable for three months on payment of eight guineas.

Chester General Infirmary.—Visiting Surgeon for two years. Salary £80 per annum, with residence and maintenance in the house.

City of Liverpool.—Visiting Physician to the City Hospital North, Netherfield-road. Salary £130 per annum. Applications to the Town Clerk, Liverpool.

County Borough of Croydon.—Medical Officer of Health for the Borough. Salary £500 per annum, increasing annually by £50 to a maximum of £600 per annum (subject to statutory deductions). Apply to the Town Clerk, Town Hall, Croydon.

Doncaster General Infirmary and Dispensary.—Indoor Dispenser and Assistant to the House Surgeon. Honorarium 20 guineas per annum, with board, lodging, and washing.

East Suffolk and Ipswich Hospital, Thorofare, Ipswich.—Second House Surgeon for one year, unmarried. Salary £60 per annum, with board, lodging, and washing.

Hull Royal Infirmary.—Honorary Surgeon.

Leicester Infirmary.—House Physician for twelve months. Salary £100 per annum, with board, apartments, and washing.

Loughborough and District General Hospital and Dispensary, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.

Mason University College, Birmingham.—Lecturer on Osteology and Chief Demonstrator of Anatomy.

Metropolitan Asylums Board.—Three appointments of Assistant Medical Officers at the Fever and Small-pox Hospitals, unmarried. Salary £160 per annum the first year, £180 the second year, and £200 the third and subsequent years, with board, lodging, attendance, and washing (subject to statutory deduction). Applications to the Clerk to the Board, Norfolk-street, Strand, W.C.

Newark-upon-Trent Hospital and Dispensary.—House Surgeon, unmarried. Salary £80 per annum, with board and lodging in the hospital.

Nottingham City Asylum.—Second Assistant Medical Officer, unmarried. Salary £125, with board, apartments, and washing.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £140 per annum. Special arrangement made as to board, &c.

Nottingham General Hospital.—House Surgeon for two years. Salary £100, rising £10 a year to £120, with board, lodging, and washing.

Paddington Green Children's Hospital, London.—House Surgeon from Feb. 1st to May 7th. Salary at the rate of 50 guineas a year, with board and residence.

Parish of Rousay and Egilshay, Orkney.—Resident Medical Officer. Salary £51 per annum. Apply to the Inspector of Poor, Rousay, Orkney.

Plymouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £125 per annum, rising to £150, with furnished apartments in the Asylum. Board and washing free.

Royal College of Surgeons of England.—Election to the Court of Examiners.

Royal Cornwall Infirmary, Truro.—House Surgeon, unmarried. Salary £85 with board (excluding stimulants) and apartments.

Salisbury Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

St. Mark's Hospital for Fistula and other Diseases of the Rectum, City-road, London.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

The Chief Inspector of Factories has given notice of vacancies for Certifying Surgeons under the Factory Acts at East Ilsley in the county of Berks, at Southampton in the county of Southampton, at Wollaston in the county of Northampton, at Edinburgh in the county of Midlothian, at Haddenham in the county of Cambridge, at Kirkoswald in the county of Cumberland, and at Thornbury in the county of Gloucester.

University College, London.—Assistant Surgeon and Assistant Physician.

University of Glasgow.—Three Examiners in Medicine. Salary attached to each is £30 per annum.

Western Dispensary, Rochester-row, Westminster.—Resident Medical Officer, unmarried. Salary 100 guineas per annum, with furnished rooms, coals, gas, and attendance. Apply to the Secretary.

West Herts Infirmary, Holly-grove, Boxmoor.—Locum Tenens for six to 12 months or longer. Salary at the rate of £100, with board, fire, lights, furnished rooms, attendance, and washing.

West Kent General Hospital, Maidstone.—Assistant House Surgeon for six months. Honorarium at the rate of £50 per annum, with board and residence.

Worcester General Infirmary.—Assistant House Surgeon and Dispenser for two years, unmarried. Salary £70 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Cooper.—On Jan. 14th, at Belsize-road, N.W., the wife of Ernest Frederic Cooper, M.R.C.S., of a son.

Dods.—On Jan. 8th, at Marylebone-road, N.W., the wife of Louis F. Dods, Surgeon, of a daughter.

Gaskell.—On Jan. 10th, at Underhill-road, East Dulwich, the wife of Leonard S. Gaskell, M.R.C.S., of a daughter.

Ionides.—On Jan. 14th, at First-avenue, Hove, the wife of T. H. Ionides, M.B., F.R.C.S., of a daughter.

Lowsley.—On Jan. 10th, at City-road, Finsbury-square, E.C., the wife of L. D. Lowsley, L.R.C.P., M.R.C.S., of Hampstead Norris, Berks, of a son.

Sanders.—On Jan. 6th, at Villa Nina, Cannes, the wife of Gordon Sanders, M.D., F.R.C.P. Edin., of a daughter.

Sturrock.—On Jan. 12th, at Home-terrace, Broughty Ferry, N.B., the wife of J. T. Sturrock, M.B., of a daughter.

MARRIAGES.

Hancock—Selfe.—On Jan. 10th, at the Church of St. Michael and All Angels, Lower Sydenham, John Edwin Hancock, M.R.C.S., L.R.C.P., D.P.H., of Hurst House, Hurst-green, Sussex, to Clara Maberly, eldest daughter of John Henry James Selfe, of "Ightham," Mayow-road, Sydenham, S.E.

Henson—Major.—On Jan. 11th, at the Parish Church, Croydon, William Warner Henson, M.R.C.S., L.R.C.P., of Impendhla, Natal, to Dorothy Wickham Featherstonehaugh Major, second daughter of the late C. M. Major, of Cromwell House, Croydon.

Jones—Burman.—On Jan. 16th, at St. Matthew's Church, Upper Clapton, by the Rev. J. Cullin, M.A., William Black Jones, M.D., B.S. Lond., of Llangammarch Wells, Breconshire, elder son of the late Rev. William Mead Jones, D.D., to Elizabeth Ada, third daughter of William Kimin Burman, of Clapton, N.E.

Mannington—Clarke.—On Jan. 4th, at Hawkhurst, Kent, Frank Mannington, F.R.C.S., of Belmont, Muswell-hill-road, N., to Lilian, daughter of E. R. Clarke, Esq., of Hawkhurst.

Plummer—Moxon.—On Jan. 17th, at St. Nicholas, Great Yarmouth, by Rev. D. M. Wauchope, vicar of New Bilton, Rugby, assisted by the Rev. Canon Rogers, vicar of Great Yarmouth, Selby W. Plummer, M.D., of Durham, to Lilian, daughter of the late Thomas Hy. Moxon, M.R.C.S., of Great Yarmouth.

Roger-Smith—Woodd.—On Jan. 10th, at the Parish Church of Hollington, St. Leonard's-on-Sea, by the Rev. Trevor Basil Woodd, rector of the parish, assisted by the Rev. T. W. Adam, of St. Peter's, Eaton-square, Hugh R. Roger-Smith, M.D., M.R.C.P., third son of Professor T. Roger-Smith, of University College, London, to Dorothy Eugenia, third daughter of the late Rev. Basil Woodd, of Leckby, Hollington Park, St. Leonard's.

Row—Harrild.—On Jan. 10th, at St. Bartholomew's Church, Sydenham, Charles Martin Row, M.R.C.S., L.R.C.P. Lond., of Pleydells, Warbleton, Sussex, to Mary Josephine, elder daughter of Horton Harrild, of Westwood, Sydenham.

DEATHS.

Castellote.—On Sept. 20th, 1899, at Kabambaré, Central Africa, Ramon Horace Castellote, M.D. Lond., F.R.C.S., son of Ramon Castellote, Salcott-road, Wandsworth common, aged 29 years.

Collum.—On Jan. 12th, at Surbiton, Robert Collum, M.D., M.R.C.S., M.R.C.P., aged 84 years.

Manbey.—On Jan. 13th, at Stanley Villa, Stanley-road, South Acton, George Manbey, M.R.C.S.

Roberts.—On Jan. 12th, at the Hawthorne, Croxley-green, Herts, John Henry Roberts, F.R.C.S., in his 87th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HYGIENE OF A HOUSE.

CORRESPONDENT has sent us some verses by an unknown poet relative to the frost and the plumber; the following are some of them. Such troubles at this season of the year are not altogether unknown, and the lines may serve, our correspondent thinks, as a text for a little advice as to what should be done in a similar emergency, pending the arrival of the necessary plumber:—

"Sing hey! sing ho! for the plumber bold!
He fears not the grip of the Ice King cold
In the bar saloon of the 'Block and Fall'
With his mate he awaits the urgent call!
When the terrified household fly in vain
As the water squirts from the bursting main,
When the thaw lets the pent up water flow,
Sing hey for the plumber bold! sing ho!"

It is far too often forgotten that a healthy house is an enormous factor in the health of the inmates, and we fear that the average householder has but the haziest idea of the construction of the various parts of a house. Damp, for instance, is productive of many evils. It is true that so far this year we have had no frost worth speaking of, and it is some years since the weather was cold enough to reproduce the miseries so vividly depicted by Leech as happening to the Briggs family. But we cannot command the weather and it is not always feasible to have the water-pipes in a house carefully packed. Every householder can take the advice given below and can learn the disposition of the pipes in a house, as to whence they come and where they go. If he knows where the taps are and how to turn off the supply he may be able to save various expenses in the matter of rotted floors and ceilings, to say nothing of illness arising from damp and its consequences. Water-supply, sewerage, and lighting are three subjects with which every householder should have some acquaintance, at least to the extent of being able to turn off the water in his house in a case of emergency. A house cannot be expected to go like clockwork, and even a clock wants some attention. Many a room has been made damp and unwholesome by leakage from a defective gully pipe. It is quite within the province of a medical man to give a little attention to these matters, so that, knowing, he may be able to instruct those of his patients who know not.

The expansive force of water at the moment when it solidifies as ice is so enormous that a very small quantity is capable of overcoming an amount of resistance out of all proportion to its bulk. When water freezes in a pipe it is seldom that it occurs at more than one or two points, unless, of course, the pipe is very much exposed. In the act of freezing the pipe is usually burst though the water cannot escape at the fracture thus made until the ensuing thaw removes the obstruction. This is the exciting moment when the terrified householder sends for the much-sought after plumber. No one can expect to be successful in acting in an emergency of this nature if at the supreme moment he is entirely ignorant of every constructive detail of the house he occupies. He should at least be acquainted with the following facts: (1) the position of the stop-valve in the main supply pipe; (2) the position of the cisterns; and (3) the destination, and, if possible, the course, of the several service-pipes from each cistern.

The situation of the stop-valve in the water company's main supply-pipe.—This is generally fixed at the nearest point to the public way, either in a cellar or sunk in the ground by the boundary fence. See that it is oiled and in working order and ascertain which way it has to be turned to open or close it.

The positions of the cisterns supplying the several fittings.—If there be more than one note which fittings each one supplies.

The destination of the several service pipes.—Every cistern should have a stop-valve in each of the service pipes leading from it at a point close to the cistern, and each valve should have a label attached stating the service which it controls whether bath, closets, sinks, &c. In the absence of such valves the services themselves should be labelled, and one or more wood plugs about four feet long with taper ends (stout broom handles will do) should be kept in readiness near the cistern. These, if properly pointed, can be inserted as a plug into either a small or large pipe at the point of connexion with the cistern. The reflection from the surface of the water renders it at times difficult to see the open ends of the pipes at the bottom of the cistern. This can be easily overcome with a candle and any kind of reflector to throw the light to the bottom of the cistern, such as a white basin or a bright dustpan, when the orifice of the pipe can be distinctly seen and the plug can be inserted into the mouth of the defective service. At any time the services can be easily traced for labelling by the insertion in rotation of the plug stick, when by trying the closets and taps it can be noted which supplies are cut off. In testing a time allowance must always be made for the amount of water remaining in the pipe, also where a closet is supplied through a disconnecting cistern it will be necessary to try a second discharge. The old pan-closets are an exception being supplied through a valve in the bottom of the larger cistern, the end of the service pipe being in this case invisible. This service, therefore, cannot burst, the pipe, excepting when the closet is in use, being empty.

A burst from frost may be either in the main supply or in one of the service pipes leading from the house cistern; this can as a rule be located before the frost breaks.

When the burst is in the main supply.—Unless during frost it is noted that the cisterns are filled daily several days may elapse before the fact is indicated by the whole house being without water. In this case at once turn off the stop valve already described. After the thaw has well set in slightly open the valve and watch the result before turning the same fully on.

When the burst is in one of the down services.—Turn off the valve or plug that particular service after which an endeavour may be made to thaw the same by artificial heat, cloths soaked in boiling water, &c. If the pipe has burst the water remaining in the pipe will soon indicate the position of the fracture, when after repair provision may be made to prevent a recurrence. In the event of a burst pipe discharging and no provision having been made to meet the emergency the pipe can be flattened. To do this draw the pipe as far as possible away from the wall and place behind it any piece of metal, such as a hammer or flatiron, to act as an anvil, and then with a few heavy blows with a hammer flatten the pipe just above the fracture. Care must be taken to strike the pipe fairly with the flat face of the hammer or the sharp edge may cut it and make matters much worse. If the burst pipe is not accessible turn off the tap of the main supply or tie up the ball valve in the cistern and run off the water through the closets, taps, &c.

Whenever frost affects the cistern or supply pipe that feeds the kitchen or any high pressure boiler the fire must be extinguished before the water in the boiler is withdrawn or evaporated. It is good policy to remember that in all cases prevention is better than cure.

"IN HIS NAME": THE RECORD OF THE R.S.U. AND SHAFTESBURY SOCIETY."

We have received from a correspondent two pages of a periodical bearing the above title. He asks our opinion of the conduct of the officials of the Ragged School Union and Shaftesbury Society as exhibited in the following little article, taken from page 6 of their presumably official journal.

> GIVING NATURE A CHANCE.
>
> On Wednesday, Dec. 20th, a demonstration of manipulative surgery and scientific massage was given by Professor Atkinson of Park-lane, in the Lower Hall, Exeter Hall.
>
> One negative advantage at the very least may be claimed for his system—the child is still *all there* when he has finished. Every surgeon cannot say as much, and we have known parents object to operations upon their children, and the children have recovered without them. In these instances there would have been the irreparable loss of members.
>
> We therefore felt justified in giving a fair chance to the "Nature assisted by Science" teaching and practice of the Professor. Accordingly, 500 cripples were brought to Exeter Hall to a treat. A number of the children were examined, with the result that a verdict was given that four out of five of the children present could be cured.
>
> The practical outcome is that there is every likelihood during the year 1900 of a representative party of the afflicted children of London being restored to soundness of limb and body.

We think on reading the above paragraphs that the parents and natural or legal guardians of 500 cripples have a distinct cause of grievance against the gentlemen who have suffered little children to come unto "Professor" Atkinson. A promise has been held out to them on no scientific grounds whatever that 80 per cent. of the crippled children can be made whole. It is cruelty thus to juggle with the hopes of the sick. Nor is it comprehensible to us why giving the "Professor" an advertisement should be called "giving Nature a chance."

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 13th there appeared an advertisement for an assistant medical officer at the Caterham Asylum of the Metropolitan Asylums Board. Having had experience of that Board I should like to point out for the benefit of intending applicants a few of the conditions under which the assistant medical officers at their asylums work. On entering upon my duties I was taken to my quarters by the steward, who apologised for the lack of accommodation offered me, explaining at the same time that such conditions were only temporary. My "quarters" consisted of one room in which I slept, the same room had also to serve me as an office, dining room, as well as for the reception of personal visitors, and indeed for every use that it is possible to put a room to. All that was temporary as far as I was concerned consisted in the facts that on committee days a screen was taken from the room, so that visitors could see the bed and the fact that I had a knob put on the door after I had occupied my quarters for three weeks. Since I left there have [illegible] particular asylum. The junior assistant [illegible] in a common dining-room and has consequently only to use his bedroom for an office and living-room generally. The medical superintendents at their asylums are not allowed to write testimonials. The Metropolitan Asylums Board, however, accept testimonials from other asylums. Such conditions prevailing one is not surprised to find that after years of service under the Board promotion is impossible elsewhere, and as the Board is not enamoured with the idea of promoting its own men the assistant medical officers find themselves in an awkward position. At other asylums it is the practice to allow the assistant medical officer the use of spare bedrooms in which to lodge a visitor, it being recognised that life in asylums is somewhat monotonous. In my time when a visitor arrived his host laid himself down on his couch (if he had one, I had not) and with his clothes on was happy that his brother from Scotland or a medical friend from America had come to see him. They were the only visitors whilst I served the Metropolitan Asylums Board. Now the Metropolitan Asylums Board will no longer allow any visitor to be the guest of their assistant medical officer overnight.

Would intending applicants for the post advertised kindly apply to any of the Metropolitan Asylums Board's medical officers for information? I am, Sirs, yours faithfully,

P. J. S.

THE DEARTH OF QUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—I noticed in THE LANCET of Jan. 13th the great difficulty of obtaining qualified assistants. I think the occasion a suitable one to bring before your notice the fact that there are at present some unqualified men who through deficient capital are unable to meet expenses of certificates and examination, though in some cases the sum is not large, and they have only the final to pass, as is my own case. It would be an unspeakable blessing to such men if you brought their cases before the profession with the object of starting a fund to enable them to qualify and overcome the difficult position they are placed in owing to the General Medical Council's regulations. I am sure they would sign any contract to repay the sum on qualifying.

I am, Sirs, yours faithfully,

Jan. 16th, 1900. UNQUALIFIED.

WIDAL'S TEST.

To the Editors of THE LANCET.

SIRS,—I would feel grateful to you if through your columns in answer to correspondents you would answer this question: What is *Widal's test for differentiation of* simple continued and typhoid fever and how is it applied? I am, Sirs, yours faithfully,

Jan. 10th, 1900. SURGEON.

* Widal's test for typhoid fever depends upon the fact that the serum of the blood of a patient suffering from that disease has a certain action upon the typhoid bacillus. The method of applying it has been slightly varied by different observers, but the following, as introduced by Dr. Johnston of Montreal can be relied upon. A drop of the patient's blood is secured, placed on a clean stick, and allowed to dry. A loop of a bouillon culture of the typhoid bacillus is placed on a clean cover-glass and to this is added a large loopful of a watery solution of the dried blood. From the mixture of blood and typhoid bouillon a "hanging drop" preparation is made and examined with a high power objective; if the patient is suffering from typhoid fever the typhoid bacilli rapidly form clumps. If the patient has not typhoid fever this clumping does not take place.—ED. L.

A SUSPICIOUS ADVERTISEMENT.

THE following advertisement appears in the *Potteries Advertiser* for Jan. 13th, 1500 —

TO LADIES.

MRS. TILSLEY requests all LADIES suffering to consult her *at once*, her treatment being simply a help to nature. All Wounds successfully treated by

MRS. TILSLEY,

114, Botteslow St. (off Charles St.), HANLEY.

We *do not quite know* what the cryptic sentence, "All wounds successfully treated" means.

VOMITING OF PREGNANCY.

To the Editors of THE LANCET.

SIRS,—*Would you or any of your readers kindly give me a hint re* the treatment of sickness in early pregnancy. I have tried cerium oxalate, hydrocyanic acid, and nux vomica without result.

I am, Sirs, yours faithfully,

Jan. 13th, 1900. OBSTET.

A SANITARY WATER-CLOSET SEAT.

THERE can be little doubt that the seat of the water-closet is sometimes a source of infection, and many devices have been suggested from time to time with a view of obviating any insanitary possibility of this sort. Mr. G. N. W. Thomas, M.B., Ch.B. Edin., of 252, Girlington-road, Bradford, sends us a sketch of a new design for a water-closet seat which he has registered at the Patent Office. The seat is circular, but fairly wide gaps are provided immediately in front and at the back, the former to avoid contagion with septic matter from the genital organs, and the latter to prevent soiling with fæcal matter under careless use. We are under the impression that a similar arrangement has been formerly proposed. There are no doubt good features in it, one distinct advantage being also that the closet may be used as a urinal with a much diminished risk of wetting the seat. It would be well if some such arrangement could be introduced into public lavatories.

◆

One Anxious to Know.—The various County Councils in most cases are responsible for the regulations. Government has nothing to do with the matter, and there is no State limit to the age of candidates. Medical superintendents have a large voice in the selection of their assistants, but we fear that the prospect of success for a man over 40 years of age is very small.

M. H. C.—The Mauser rifle bullets are of varying size according to the calibre of the rifle, but the mean weight is about 200 grains. The Lee-Metford—i.e., Mark II., Mark IV., and the Dum-Dum—bullets all weigh the same—namely, 215 grains.

Locum should be careful not to break the spirit of his undertaking whatever the letter may be. He must consult a solicitor as to his legal position What he wishes to do does not commend itself to us.

J. B.—If nothing has been pre-arranged in the matter we think a week's notice must be accepted.

A. J. P., Leeds.—We are making inquiries.

Verax can sign the certificate.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W C)—4 P M *Dr Garrod: Demonstration of Selected Cases.*

CHARING-CROSS HOSPITAL.—4 P M Dr Bruce: Medical Cases (Post-graduate Course.)

FRIDAY (26th).—MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—4 P M. Dr StClair Thomson: Consultation. (Eye, Ear, Nose and Throat.)

During the week marked copies of the following newspapers have been received *Brighton Gazette East Daily Press (Norwich), Lloyd's Weekly Newspaper, Hull Daily Mail Morning Herald Dundee Advertiser Leicester Daily Post, Nottingham Daily Guardian Wigan Observer Glasgow Herald, Leeds Mercury Nuneaton Observer, Retford Record, Kentish Observer Midland Counties Herald, Times of India, Pioneer Mail, Cheltenham Mercury Surrey Leader, Whitby Gazette, Western Mail, Western Morning News, Bradford Observer, Express and Star Ealing Guardian, Warrington Guardian, Scotsman, Architect, Builder Citizen Liverpool Daily Post Health, Bristol Mercury Sanitary Record, Yorkshire Post Indian Textile Journal, Leeds Mercury Cheltenham Examiner Hereford Mercury First Aid, Poole Herald Le Courrier de la Presse Mining Journal, City Press Local Government Chronicle Hertfordshire Mercury Jackson's Oxford Journal, Reading Mercury Birmingham Daily Mail, British Dental Journal Beverley Guardian, Normanton Herald, Kent Herald Potteries Advertiser Surrey Advertiser Local Government Journal, Weekly Free Press and Aberdeen Herald, Kilmarnock Herald Tewkesbury Record Highland News (Inverness) Ballymoney Free Press, Birmingham Daily Post, Western Telegraph (Croydon), &c, &c*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession may be sent direct to this Office

Lectures, original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed 'To the Manager'*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol II of 1899, which was completed with the issue of Dec 30th, and the Title-page to the Volume were given in THE LANCET of Jan 6th

---

VOLUMES AND CASES

VOLUMES for the second half of the year 1899 are now ready Bound in cloth, gilt lettered, price 18s carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2s, by post 2s 3d

To be obtained on application to the Manager, accompanied by remittance

---

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, W C, are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET *Offices or from* Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance

---

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and agents are authorised to collect and do so collect from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied, *Address*—THE MANAGER THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

A Clinical Lecture

ON

SLEEPLESSNESS

Delivered at the Medical Graduates College and Polyclinic on Jan 17th, 1900,

BY SIR WILLIAM H BROADBENT, BART, M D, F R C P LOND, F R S,

PHYSICIAN EXTRAORDINARY TO H.M THE QUEEN; PHYSICIAN IN ORDINARY TO H R.H THE PRINCE OF WALES CONSULTING PHYSICIAN TO ST MARY'S HOSPITAL.

GENTLEMEN —Sleeplessness is one of the torments of our age and generation and we are daily called upon to treat it but I could not well bring cases before you for demonstration While, however, I have no actual patients to present and shall not even read notes of cases, it is incumbent on me to treat sleeplessness from a clinical point of view I am fortunately therefore, under no necessity to discuss the various theories of sleep, nor have I to entertain you with speculations on the neuron or as to the behaviour of dendrons during sleep such as those which now seem to be the inevitable introduction to all questions in which the nervous system is concerned—to attempt to explain, in effect, the *ignotum per ignotius*, which has a perennial fascination

One word, however, must be said as to difference in the vascular condition of the cortex of the hemisphere in the sleeping and the waking state According to old experiments the cerebral cortex is in a condition of anæmia during sleep and it has been assumed that the blood is shut off by contraction of the arterioles but we have been assured by Dr Leonard Hill that the vaso motor regulation of the blood supply does not extend to the brain, that no nerves are distributed to the cerebral blood vessels, and that it has been demonstrated by experiment that the blood pressure within the cranium is entirely controlled by the ebb and flow of the blood in the splanchnic area On the other hand my friend Dr Alexander Morison shows beautiful preparations of arteries from the pia mater in which these vaso motor nerves are conspicuously visible and independently of this direct evidence, one was disposed to wonder why these vessels had muscular walls if there were no nerve supply It seems to me that the only possible explanation of many of the disturbances of the functions of the brain from peripheral irritation of various kinds is a reflex influence of the cerebral circulation

In this lecture I propose to limit myself to the consideration of sleeplessness where it constitutes the special complaint on account of which the patient seeks advice To speak of loss of sleep where it is only one among many symptoms of disease of brain lungs, or heart, or one of the effects of fever or other acute affection, would require two or three lectures

Sleep consists essentially of a suspension of the functions of the higher centres of sensation or rather perception involving inaction of the corresponding motor centre The reflex action of the cord persists as well as the vital reflexes concerned in respiration and the action of the heart. Reflexes also survive in which there is a considerable degree of purposive coördination, the extremities will be withdrawn from a source of irritation and we turn over in bed and may adjust bedclothes without waking The Indian thief will steal the blanket from under the sleeper by so tickling him that he rolls over first in one direction and then in another While sensation is suspended a loud noise or a bright light, a shake or a sharp impression on the surface will penetrate the barrier opposed to impressions and rouse the sleeper, and many persons have the faculty of waking at a given hour Most of us, indeed, can wake up to catch an early morning train in case of need The intensity of the respective sensory impression required to disturb sleep varies greatly in different individuals and in the same person at different times A susceptibility to the disturbing influence of light and sound can be cultivated by sleeping in darkened rooms and with closed curtains On the other hand habit enables a Londoner to sleep not only in spite of the more or less continuous roar of traffic but through the thunder of a railway waggon or a post office van tearing along a quiet street, and many persons can sleep in broad daylight

It may be said at once that the treatment of sleeplessness does not resolve itself into a choice of drugs To compel sleep by opiates or sedatives is not to cure sleeplessness It is true that when the brain has been overtaxed by engrossing work, or the nervous system has been shattered by a severe shock or exhausted by overwhelming anxiety or outworn by excitement or the habit of sleep has been broken by long and anxious vigils over a sick bed, a judiciously selected remedy may quiet the molecular vibrations and restore self control to the brain and so break the wakeful habit and renew the patient's confidence Setting aside these exceptional cases the sedative whatever it may have been, may leave the cause of sleeplessness untouched, and while this remains in full operation the nervous system becomes accustomed to the drug and a larger and larger dose is required Then, moreover, the effects of the drug are not confined to the production of sleep The substance is carried by the blood everywhere and it may check secretions, derange digestion, impair the peristaltic vigour of the stomach and intestine, affect the circulation and deteriorate the blood, and interfere with the nutrition of the tissues One effect all drugs have, and always have—they diminish the resistance and impair the manhood of the individual It is not only that he has experienced relief and that he longs for it again, but he will not endure with patience and fortitude a privation of sleep which he would formerly have thought unimportant So it goes on until the morphia habit is established or the patient becomes a slave to chloral or sulphonal or trional Nothing is easier than to obtain a cheap kind of credit by prescribing a sedative, especially if its name is new to the patient and he can be assured that he is not taking an opiate properly speaking, but it may be the first step in the downward course towards suffering, bodily and mental, of the most terrible kind From what I have seen I should prefer to be a victim to morphia or to opium rather than to chloral or to sulphonal or to trional If the reaction from the opium intoxication is painful there is at any rate a positive pleasurable exaltation, whereas the best that chloral and sulphonal can give is oblivion and there is not only depression but a pitiable loss of volition The wretched subject cannot make up his mind on the most trivial question and when he has come to a decision he regrets it immediately Besides this indecision there is loss of memory, and either from this loss of memory or from impairment of the moral sense no dependence is to be placed on his statements The heart and the vessels lose their tone, the circulation becomes languid, and the tissues grow soft and flabby, till finally the victim is incapable alike of effort and enjoyment Unfortunately these drugs are placed within the reach of all in the form of syrups and tabloids, there is no restriction on their sale, and they are constantly taken on the advice of chemists or friends The medical man who prescribes any of them has thus no further control over their administration and incurs therefore a terrible responsibility

The essential preliminary to the treatment of sleeplessness is the recognition of its cause in the particular case We have therefore to consider the causes of sleeplessness Of these the most important undoubtedly is the original constitution of the nervous system The capacity for sleep and the readiness to sleep vary enormously in different persons Some can command sleep at a moment's notice almost at any time and under any circumstance, with others sleep always requires careful wooing But while there are inborn differences in this respect manifested even in infancy, much can be done to bring the nervous system into a condition which favours sleep or the reverse and this is a point always to be borne in mind in the treatment of sleeplessness Of all the influences which tend to bring the nervous system into a state in which sleep is ready, sound, and refreshing, the most important are fresh air and exercise A sedentary mode of life has a contrary effect. Besides therefore, protecting the light sleeper from all causes of sleeplessness and removing any which may be identified, it may sometimes be necessary to revolutionise his habits and to lay down special rules as to his mode of life The old distich "After dinner rest awhile after supper walk a mile" seems to have been written for the benefit of such an individual

These naturally bad sleepers are greatly to be pitied The slightest change in the bed or of pillows or coverings will give a bad night, the pillow must be h and it must be soft and low for others. Sleep in a strange room is for a time impossible. A chink in a shutter, or a badly-fitting blind, or ill-adjusted curtain admitting a single beam of light will cause some to wake up at daybreak. Some must have absolute darkness, others require a certain degree of artificial light. It is in such cases that the great difficulty arises of deciding whether sedatives of one kind or another may be given. Much depends on the kind of sleeplessness. If the patient can lie quiet and, while sleepless, remain tranquil, I should hesitate to give drugs. He has rest even if he does not sleep and very commonly there is sleep of which he is not conscious. An occasional dose may be given to parry the effects of any unusual excitement or fatigue The choice of the drug would be determined a good deal by the experience of the individual, but if the pulse-tension were high chloral would be indicated as a vascular relaxant; if it were low, paraldehyde or bromide or some such combination as morphia and hyoscyamus. When the patient tosses and fidgets and gets up looking worn and tired there is more need to have recourse to sedatives and it is extremely likely that their use will become more or less habitual. If possible bromides should be the drugs employed. There are cases in which a moderate dose of ammonium bromide just seems to bring the irritable and sensitive nervous system to an average condition and I have known patients to take it indefinitely without apparent injury. I cannot say this of any of the chloral or sulphonal class of drugs.

There are conditions of the circulation which interfere with sleep. Perhaps the most easily recognised of these is coldness of the feet. Anæmic girls are often kept awake by cold feet, and in debility from other causes coldness of the extremities may prevent sleep. For sleeplessness so caused a hot bottle is the obvious remedy, or, perhaps better, enveloping the legs in warm flannel up to and above the knees, which will usually be felt to be cold as well as the feet. Such patients should be warned not to dawdle while undressing but to change and get into bed quickly, and the feet should be vigorously rubbed. To anything of this kind, however, they are indisposed by the very languor and weakness which give rise to the coldness of the extremities. A great help to sleep in patients suffering from sluggish circulation is a little very hot and strong beef-tea or hot milk on going to bed. Stimulants should be avoided in the case of the young; there is less objection to them in elderly people, but in them the stimulant should not be relied upon simply as such, but should be given in the form of a hot drink, such as negus or spirit and hot water. Cold feet may prevent sleep when there is no weakness of any kind after hard intellectual work, especially when carried on late into the night. It is not a mere negative coldness which can be rectified by supplying warmth; external heat seems to be rejected and the feet refuse to be warmed by it. There is, in fact, spasm of the arterioles excluding the blood, just as when the feet are stone cold in fever while the temperature in the mouth or rectum is 103° F., and it may be pointed out that when the extremities are warmed by the application of external heat the warmth is not simply supplied from without; the vessels are relaxed by the heat applied to the surface and the warm blood is admitted. Under the circumstances we are considering, the reflex vaso-dilatation does not take place and the hot bottle, even if available, is of no use. The resource is friction, but this has to be persevered with for some time to be effectual. To stand in cold water for a few minutes before rubbing the feet is an excellent expedient, resorted to, as I have found, by many hard-working friends and to which I can bear personal testimony. Hot beef-tea or milk would be invaluable, or even a drink of hot water, but brain-workers are too much engrossed with the task in hand for forethought to provide these remedies. I would particularly warn my young hearers who may be sleepless after hard work against opiates. They may be most effectual and may not seem to disturb the digestion or interfere with work next day, but I think the judgment is liable to be impaired so that dominant ideas are not adequately tested and get the upper hand, while the ultimate results may be disastrous.

Sleeplessness may be due to an exactly opposite condition—a hot burning feeling in the feet which, however, more commonly wakes the patient up than prevents his getting to sleep. It may be part of a general sense of heat and discomfort attending gout, or sub-acute rheumatism, or rheumatoid arthritis, when the feet may be really hot, or the sensation of heat may be subjective only, (while the feet are cold to the touch and deep crimson in colour. Patients will often insist on putting the feet out of bed, but the relief thus obtained is only partial and temporary. The treatment of the sleeplessness will be that of the underlying condition. If an opiate is required, as may be the case, especially when there is pain, an old-fashioned Dover's powder is one of the best vehicles and there is little danger of its laying the foundation of the opium habit. Or phenacetin or antipyrin may afford relief and find a legitimate opportunity of usefulness.

Conditions of the circulation which do not give rise to such conspicuous effects are very frequently attended with sleeplessness. One of these is high arterial tension. It may be supposed that the high blood-pressure does not permit the arterioles to shut off the supply and reduce the cortical circulation. Whatever the explanation may be the cases are very common in which high arterial tension and sleeplessness go together and in which the lowering of the one affords relief to the other. Since the presence in the blood of nitrogenised waste is one cause of high tension the treatment dictated is to minimise its formation and promote its elimination. The patient will be put on a regulated diet in which the proportion of animal food will be adjusted to the individual requirements. In this the patient's previous habits and dietetic idiosyncracies must be taken into account. Nothing can be more absurd than to lay down rules to be applied indiscriminately to all sorts of constitutions. A glass of water night and morning is usually a good thing. Among the most efficacious of the eliminants is a mercurial aperient which, as it may have to be repeated once or twice a week for a long time, must be mild. A single grain of calomel or one or two mercurial pills or mercury with chalk with colocynth and hyoscyamus, or compound rhubarb pill, is usually sufficient and may be taken twice a week indefinitely. The eliminant action of the mercurial aperient may be followed up by mild salines or by alkaline tonics.

Rare instances are met with in which an exactly opposite condition—extremely low tension—appears to give rise to sleeplessness, or at any rate makes sleep in the horizontal position difficult or impossible. In the sitting position these patients can scarcely keep awake; at any period of the day they will drop off to sleep if they sit down and try to read; and even over the morning newspaper and after dinner they will sleep indefinitely until they go to bed and lie down when at once they are wide-awake. It seems as if the toneless vessels were incompetent to resist the slight increase of pressure within the cerebral vessels when the patient lies down. The treatment here must obviously be tonic.

By far the most common cause of sleeplessness is indigestion in its various forms, and the particular incident of indigestion which seems to be the most active antagonist of sleep is flatulence, especially gaseous distension of the stomach. Apparently it is mechanical pressure or stretching which prevents sleep, since sleep often at once follows the eructation of a few cubic inches of gas. The volume of gas displaced is quite insufficient to affect the splanchnic circulation, and it is not easy to understand in what direction the pressure operates which produces the result. There may be extreme dilatation of the stomach from pyloric obstruction without serious influence on sleep, and whenever the stomach has been displaced downwards, so that the lesser curvature is defined on the abdominal wall, or can be followed by palpation, I have found that the effect on sleep was little marked. When, on the other hand, the upper line of gastric resonance has been high, corresponding with the fifth space and the base of the ensiform, sleeplessness is common even though the area of resonance may not be very extensive. It does not follow that when flatulence is the cause of sleeplessness the patient should suffer from the ordinary symptoms of flatulent dyspepsia, epigastic pain or discomfort, and frequent eructations. Flatulent distension of the stomach produces its worst effects when we are not conscious of its existence. When we suffer from flatulence in the ordinary sense of the word what we are conscious of is not the flatulence itself but the effort to get rid of or displace it. When it is tolerated by the stomach and no effort is made to expel it its more serious effects are produced—anginoid pain in the cardiac region, palpitation of the heart, and sleeplessness. It will be clear from what has been already said that the form of dyspepsia attended with sleeplessness is that in which the special characteristic is atony of the muscular walls of the stomach, allowing of the passive distension of the organ. A further inference will be obvious—that it is in brain-workers whose nervous energy is diverted from the work of digestion, or in those whose mode of life is sedentary and whose general nerve-tone is low, or in persons depressed by anxiety and worry, that this form of dyspepsia is most liable to occur. One way, indeed, in which grief and worry and anxiety give rise to protracted sleeplessness is through the effects on digestion. Sleep will come to the relief of grief and even anxiety gives way to weariness and sleep, but nothing is more certain than the effect of mental depression on digestion, and when the sufferer is roused by flatulence or abdominal discomfort the distressing or agitating idea takes possession of the mind and banishes further sleep. Flatulent dyspepsia, again, is one of the causes of the sleeplessness which is said to belong to old age. It is not old age as such to which sleeplessness is to be attributed but to the infirmities attending it—to vascular conditions or functual derangements of one kind or another of stomach, bowel, or bladder. Flatulent dyspepsia very often interferes with sleep on first going to bed and may keep the sufferer awake indefinitely. This faculty it shares with various causes of sleeplessness, but one very common variety of sleeplessness is highly characteristic of flatulence. The patient, possibly a good sleeper naturally, falls asleep on getting into bed and then wakes punctually night after night at a given hour, at two o'clock, three o'clock, or four o'clock as the case may be, and then lies awake for the rest of the night. The explanation is that the last meal has not been entirely passed on into the duodenum. Fermentation takes place in the food which remains in the stomach and after a certain time sufficient gas and acidity have been developed to disturb the sleep.

The treatment of sleeplessness due to flatulence is, of course, that of the dyspepsia. This in itself would demand an entire lecture for its discussion and you will not expect me to enter upon it. All I need do is to enumerate the expedients for preventing the interference with sleep. The simplest of these is a tumbler of hot water at bedtime, and it is usually effectual. The stomach is stimulated to contract, much of the gas present in it at the time is expelled, and any fermenting contents are swept on into the small intestine where the antiseptic bile checks further fermentation and where flatulence gives rise to less disturbance. The hot water should be taken before undressing so that it may have time to clear out the stomach and expel the gas before the patient lies down. Should hot water not be sufficient sal volatile and carbonate of soda may be taken before it or an alkaline carminative draught may be given—carbonate and sulpho-carbolate of soda with aromatic spirit of ammonia, compound tincture of chloroform, or ether and peppermint or camphor water and sometimes bromide of sodium or ammonium may be added with advantage for a time. Friction over the epigastrium or between the shoulders may help to disperse the flatulence. I do not think it is well to allow even so simple and harmless a matter as a nightly dose of hot water to grow into a habit. As a rule it should not be continued for more than a week at a time as the response of the stomach becomes imperfect. It has seemed to me that an alkaline draught can be taken longer without losing its effect. I know several patients who wash out their own stomach at bedtime whenever they have sensations which lead them to apprehend a bad night.

Some individual causes of sleeplessness must be considered. Tea and coffee are looked upon as powerful agents in the prevention of sleep and there are no doubt many here who have found a cup of strong tea or coffee an excellent preparation for an evening's work. Certain kinds of tea and really good coffee do undoubtedly act as stimulants to the brain; they help the tired nurse to keep awake and fresh, and keep sleep at bay for the student who is working far into the night. They may, indeed, produce a condition of intense wakefulness. When, however, it is stated that a cup of tea in the afternoon will keep a given person awake all night, I doubt very much whether it is the tea, as such, which is responsible for the result. Imagination often plays a very influential part in the effect Let such a person be confidently assured that pure China tea, brewed for not more than two minutes, is innocent of such evil properties and he or she will often take it with impunity whether it conforms exactly to the description or not. But afternoon tea is a very common cause of flatulent dyspepsia and in this way may be responsible as the cause of protracted sleeplessness. So with the after-dinner cup of black coffee, it is often the dinner and not the coffee which disturbs the night's rest

Influenza has familiarised us with sleeplessness of a most obstinate character. There is always asthenia, cardiovascular and nervous, which must be borne in mind in the treatment. With the general effect on the nervous system there may be complications which contribute seriously to the prevention of sleep and may even interfere with the action of powerful opiates or sedatives. Among these is acute dilatation of the stomach, a not uncommon incident of an attack of influenza. It was present in the worst case of post-influenzal sleeplessness that I ever saw, in which there was not a wink of sleep for four days and nights. Sleeplessness following influenza must be treated as an acute affection and, unless there is speedy improvement under such tonics as arsenic or phosphorus, strychnine and quinine, together with measures for the relief of functional derangements, opiates may be given without hesitation and I think it better to have recourse at once to combinations of opium or morphine and hyoscyamus with carminatives than to try sulphonal, or trional, or chloral and bromides. In case of need morphine may be given hypodermically and it usually adds greatly to the efficiency to combine it with strychnine as well as atropine. The immediate effect of large doses of alcohol is torpor. A result of long-continued alcoholic excess is sleeplessness culminating in delirium tremens. The remedy here is total abstinence with considerable doses of strychnine or nux vomica and perhaps digitalis. At the same time the liver and stomach disorders resulting from the alcohol will demand attention as they may keep up the sleeplessness and are indeed frequently its main cause

I do not know whether it is worth while mentioning some of the popular remedies for sleeplessness. Among them is the hop pillow which certainly sometimes seems to soothe. There is, again, the saffron bag applied to the pit of the stomach immortalised by Bulwer Lytton in "The Caxtons." Gently smoothing the hair is undoubtedly efficacious in many cases, as is also, but less frequently, sponging the burning palms. Dipping the face in cold water is one of the expedients of the worker late at night; some will sponge the entire head. Then there are the different ways in which people try to hypnotise themselves by watching and counting the invisible breath, slowly counting imaginary sheep as they pass through an imaginary gate, and the like. I have not ventured on the large subject of the employment of hypnotism. That it has its legitimate uses in inducing sleep I have no doubt. It has not been my good fortune to meet with a case where it has overcome the morphine habit or rescued the victim of chloral or sulphonal.

THE PROCESS OF DIGESTION AFTER RESECTION OF ABOUT SIX FEET OF THE SMALL INTESTINE.

BY PROFESSOR CARL SCHLATTER,
OF THE ZÜRICH SURGICAL KLINIK.

(*Translated for* THE LANCET.)

BEFORE proceeding further, the title of this paper requires some explanatory observations. The dimensions of the intestine when in the living body or when only just removed from it are, as every surgeon knows, subject to great variation. Surprisingly different results are obtained according as the bowel is measured in the completely collapsed con dition or when containing gas and distended. In illustratio of this mention may be made of an intestinal resection pe formed by me in a case of strangulated gangrenous herni some weeks after the operation which is the subje of this paper. The piece of intestine as it lay o the table in the relaxed condition measured barely 50 cen metres (20 inches) in length, but when I, in order test the resistance of the necrosed portion, filled the tine with water, not using any additional force, the portion underwent elongation to 90 centimetres (3 Trzebicky[1] has also called particular attentio variations in the length of the intestine. T intestine removed in resection is generally co its size, on which account measurements taken at that time must lead to delusive results. When I specify 192 centimetres as the length of the portion of the intestine resected in the present case it is to be carefully kept in mind that this number expresses the shortest length—i.e., what Trzebicky calls the deceptive measurement in the case of resected and contracted intestine. In order that accurate comparisons of this case with others may be made it is necessary at the outset to allude to this question of disparity in methods of taking measurements. For the due appreciation of a reduction of the absorbent area of the intestine there is an essential preliminary question: What proportion of the intestinal tract is removed in resection? The statements of text books with regard to the total length of the intestine vary considerably; one[2] gives five and a half metres (18 feet) as the length of the small intestine, while another one[3] gives eight metres (26 feet). Beaunis and Bouchard specify as the limits four metres and eight metres (13 feet and 26 feet); Trzebicky finds values ranging from 561 centimetres to 870 centimetres (from 18 feet 5 inches to 28 feet 9 inches); Vierordt finds values ranging from 560 to 770 centimetres (from 18 feet 5 inches to 25 feet 5 inches), the length of the large intestine being given as from 130 to 230 centimetres (from 4 feet 3 inches to 7 feet 6 inches). According to Beneke the ratio existing between the total length of the body and the length of the intestine is that for every 100 centimetres of the former there are 387 5 centimetres of small intestine (without the duodenum) and 91 5 centimetres of large intestine. The height (*Korperlange*) of our patient being 172 centimetres (5 feet 8 inches), in accordance with the last of these estimates the length of the small intestine might be taken to be 666 centimetres (21 feet 10 inches). The portion resected would therefore amount to rather less than one-third of the total length of the small intestine.

---

[1] Ueber die Grenzen der Zulässigkeit der J Archiv für Klinische Chirurgie, Band xlviii., p. 63.

To what extent may the human intestine be removed without entailing, if not actual death from inanition, at least serious interference with the function of absorption persisting as long as food continues to be supplied? This question is of great interest to the physiologist and under certain circumstances is also of the utmost practical importance to the surgeon. Attempts to discover the answer have been made in a variety of ways, and have led to valuable observations. Senn[4] first proceeded by the method of making experiments on animals. Of seven extensive resections of the small intestine performed on dogs and cats only two were available for the purpose in view. *In both cases an intense*, long-continued, and eventually fatal marasmus was the sequel of the resection. As the result of these experiments Senn came to the conclusion that excision of more than one-third of the whole length of the small intestine was an operation dangerous to life, productive of marasmus, and in this way fatal sooner or later. He also directed attention to a compensatory hypertrophy of the intestinal wall. Trzebicky assigned much wider limits for the intestinal resections permissible in dogs, supporting his conclusions by extensive resections of the small intestine performed by him on 28 animals. "Resections of half the small intestine were tolerated quite well; resections of two-thirds and upwards of the jejunum and ileum made such an inroad on the chemical and mechanical processes of digestion that the prolongation of life became impossible." There was incessant diarrhœa, followed at a later stage by vomiting; food was voided for the most part undigested, and in spite of a craving appetite the animals perished with symptoms of complete inanition. Trzebicky made an observation of even greater importance—namely, that the results of resection of the beginning of the jejunum *were more serious than those of resection further in the* direction of the ileo cæcal valve. He attempted to apply to the human subject the results which he had obtained and declared that the shortest length of the small *intestine being taken as 560 centimetres (18 feet 5 inches)* esection of one-half of it—i.e., 280 centimetres—was uite permissible, presuming that no further complications present. Monari[5] did not consider that the limits d by Trzebicky were conclusive. The inferences from his experiments, likewise made on dogs, even permitted a resection of seven-eighths of the small intestine without the production of important interference with metabolism. He believed that at least one-half of the small intestine might be removed in the human subject without the person's metabolism being influenced for the worse. In like manner with Senn, he also found hypertrophy and hyperplasia of the gastro-intestinal tract in the dogs which had been operated on.

The address delivered by Dreesmann[6] at the last congress of German naturalists and medical men held at Dusseldorf supplied us with a summary of the extensive resections of the intestine which have hitherto been performed on the human subject, a summary for which our thanks are due to that author. *Including the one observed by himself he* found a total of 26 cases in which more than one metre (39½ inches) of the small intestine had been removed. The ultimate results shown by the statistics were not particularly brilliant. Of the 26 patients 17 survived the operation and five of the latter suffered from disorders of the digestive tract, leaving 12 whose digestion remained subsequently unimpaired. It is to be noted that in 10 of the last-mentioned cases the portion of intestine removed was less than two metres (6 feet 7 inches). Up to the present time six resections of more than two metres of the bowel have been successfully performed—namely, 205 centimetres of the small intestine (Koberle), 208 centimetres of the small intestine (Kocher), 215 centimetres of the ileum (Dreesmann), 234 centimetres of the ileum (Shephard), and 310 centimetres of the ileum (Fantino). The sixth and most extensive resection was that made by Ruggi—namely, 330 centimetres of the small intestine in an eight-year-old boy on account of circumscribed peritonitis. Subsequent disorders of the digestive tract occurred in four of these extensive resections, only two remaining exempt from them—namely, the first performed one with 205 centimetres removed, and, strange to say, the last one with 330 centimetres removed. Evidently this most unusual case of Ruggi's can be explained only by the youthfulness of the patient in question, for in early life compensatory hypertrophy of the remaining intestine can establish itself much more easily than in the adult. From these statistics Dreesmann draws the inferences (1) that resections of less than two metres do not provoke any disorders of the digestive tract except when complications are present; and (2) that resections of more than two métres may be performed without subsequent disorders of the digestive tract, provided that the patients are young. The disorders referred to manifest themselves chiefly as diarrhœa.

Fantino's case[7] of resection of 310 centimetres (10 feet 2 inches) of the ileum deserves special consideration. The patient was a woman, 60 years of age. Notwithstanding her deficient assimilation of nutriment an increased supply of food succeeded in preventing emaciation. Fantino concludes his communication with the statement: "At all events, an important fact is now established—namely, the possibility of resecting three metres of the small intestine of an aged patient, provided that he or she possesses a normally-acting digestive apparatus."

With respect to the limits which are permissible in intestinal resection in the human subject it will be perceived from the foregoing short summary that opinions based on experiments made on animals present considerable divergencies. Extensive intestinal resections already performed on the human subject would supply a safer foundation on which conclusions might rest, but these operations are so few in number that any addition to the existing statistics of only six cases is very welcome. The account now to be given contains the essential particulars of the clinical history of a patient upon whom I operated in autumn, 1898, and whose small intestine was resected to the extent of about two metres, a length which nearly approaches the critical dividing line.

On the evening of Oct. 9th, 1898, there was a great disturbance and stabbing affray among Italians in Zürich, in the course of which a man, 23 years of age, was stabbed in the hypogastric region at 7 P.M. He immediately fell down and observed that his intestines protruded from the wound. His companions then conveyed him home, a distance of about 300 metres (320 yards); he did the whole journey on foot, being supported only underneath the arms. A medical man who was fetched an hour or two

afterwards applied a first-aid dressing and directed the removal of the patient to the surgical klinik. The patient eventually arrived at the Surgical Poliklinik (i e., out-patient department) in a municipal ambulance vehicle at 3 A M. on Oct. 10th, accompanied by three other Italians who had been stabbed. He was a man of middle size, strongly built, and well nourished; his mind was quite clear; his pulse was fairly strong, regular, and over 100; his extremities did not feel particularly cold; his thoracic organs presented nothing unusual After removal of the first aid dressing there was found lying on the right hypogastric region a voluminous coil of small intestine the length of which was estimated at two metres (six feet seven inches). The greater part of it was in colour from deep dark blue to black; the serous membrane was quite lustreless. At 4 A.M.—namely, nine hours after the infliction of the wound—the patient was anæsthetised with ether. After shaving the hair, the abdominal walls and especially the edges of the wound, together with the piece of intestine, were cleansed and sterilised with solution of corrosive sublimate (1 in 5000). The protruding intestine was tightly grasped by the little wound and was already in part undergoing necrotic change, so that reposition was not to be thought of and the only hope lay in total resection. With some trouble I succeeded in drawing the two ends of the piece of bowel further out of the wound in order that the resection might be performed in healthy tissue. After application of Wolfler's compressors to the healthy parts of the bowel at both ends and the shutting off of the affected parts by means of Péan's clamps at both ends, the bowel was cut through with scissors at one side, the healthy extremity cleansed with pads of iodoform gauze, and then the long piece of mesentery divided as far as the healthy portion of the other end of the piece of bowel, Péan's clamps being applied in rapid succession to the line of attachment of the bowel. The bowel was now cut through at the other end in front of the Wolfler's compressor, and the numerous clamps on the mesentery were replaced by ligatures. The edges of the gap in the mesentery were united by a row of interrupted silk sutures, so that the two intestinal orifices were made to meet one another by folding the peritoneum. The suturing of the two ends of the bowel was done in the following way. The edges of the serous membrane were first of all united posteriorly with a continuous silk suture, then those of the mucous membrane were united round the entire circumference, and finally, the edges of the serous membrane were brought together anteriorly. For greater security a third layer was added, consisting of a row of Lembert sutures in the serous membrane The original wound in the abdominal wall, the narrowness of which had hitherto been regarded as a desirable shutting-off of the abdominal cavity from external infection, was now for the first time enlarged by an incision about five centimetres (two inches) long for the purpose of replacing the sutured parts It was then found that the incision in the skin had formed the real constricting ring, the primary peritoneal wound being notably larger. The wound was about three fingers' breadth above the centre of Poupart's ligament on the right side and parallel to it; its length was a centimetre and a half (0.6 inch); its edges were quite smooth. After replacement of the sutured parts no effusion of blood was found in the abdominal cavity, neither were there any indications of perforation of the bowel The wound was therefore completely closed by a continuous silk suture of the peritoneum and an interrupted silk suture of the muscles and the skin. The dressing consisted of iodoform gauze and adhesive plaster. The length of the portion of intestine removed was 192 centimetres (six feet four inches) From the corrugation of the mucous membrane it was obvious that the whole of it belonged to the ileum.

On Oct 12th a note was made to the effect that the patient had scarcely suffered at all from the consequences of the operation. There was some vomiting when the anæsthesia was brought to a close The highest temperature hitherto attained was 37.8° C (100° F) on the evening of the second day. Some tea was given to him by the mouth on the day of the operation. On this day for the first time a stool was passed of semi solid (breiiger) consistence. On the evening of the 14th the temperature, which had not hitherto been febrile, suddenly rose to 38.3° C (101° F) and a copious eruption of urticaria appeared over the whole body. On the 16th it was noted that there was a complete absence of abdominal symptoms, the urticaria, however, still continued. The evening temperature on the previous day had been 39.8° C (103.8° F) but there had been a reduction in the pyrexia since then and the evening temperature now was 37.5° C. (99.4° F.). On the 17th the dressings were changed for the first time. The wound was healthy and had firmly united; the sutures were removed. The urticaria was fading. On the 19th the urticaria had disappeared. On the 20th, while the dressing was being changed, some pus was evacuated by pressure on the lower part of the wound; there was no redness at that place and the pus evidently came from the muscular layer of the abdomen. On the 20th the patient's evening temperature rose to 38° C. (100.4 F.) in consequence of his having eaten a fried sausage that day; on the 21st, however, he presented no abdominal symptoms. On Nov. 3rd the patient felt perfectly well; his weight was 64 kilogrammes (140¾ lb.) and he was on full diet. He was allowed to stand on the 9th. His weight on the 15th was 68 kilogrammes (149½ lb). On the 29th it was 73 kilogrammes (160½ lb), so that he had gained nine kilogrammes (19¾ lb) during the preceding three weeks. On Dec. 7th he was discharged recovered. He weighed 75 kilogrammes (165 lb), his appetite was always hearty, and his bowels acted regularly almost every day. The young man's strength was good and he presented an appearance of exuberant health. He would have willingly resumed his work as a hodman if want of employment in consequence of the winter season had not compelled him to return to Italy.

The foregoing clinical history unquestionably shows that in the case of a powerful, well developed man, 23 years of age, the loss of nearly two metres of the ileum was tolerated without the slightest subsequent derangement of the health. On ordinary hospital diet the patient remained perfectly free from any troublesome symptom, not even diarrhœa being experienced. Only one complication interrupted the normal progress of his recovery—namely, the appearance of urticaria over his whole body on the fifth day after the operation, this being a complaint from which he had never previously suffered. The relationship of cause and effect between the exanthematous condition and the immediately preceding operation on the intestine may be taken for granted, because disorders of the digestive organs often lead, both by their purely reflex and their chemical effects, to diffuse erythemata and urticaria.

In order that an opinion might be formed as to the conditions of intestinal absorption in the patient the assimilation of the ingested albumin and fat was followed up for nine consecutive days. I have to thank Dr. Plant, scientific assistant at the Zürich Cantonal Hospital, for carrying out the researches which led to the results now exhibited Special importance was attached to leaving the patient on ordinary diet as he was, with the most complete freedom of choice as regarded the nature and quantity of what he consumed. The investigations were made very laborious by the introduction of the last mentioned considerations, but it was only when carried out in this way that they were able to give a correct insight into the habitual capacity for absorption possessed by the remaining portion of the intestinal tube. The man's daily consumption of food fluctuated between from 400 to 800 grammes (from 14 to 28 ounces) of milk, from 200 to 450 grammes (from seven to 16 ounces) of coffee, from 307 to 372 grammes (from 11 to 13 ounces) of meat broth, from 420 to 643 grammes (from 15 to 23 ounces) of soup, from 260 to 345 grammes (from nine to 12 ounces) of potatoes or 317 grammes (11 ounces) of maccaroni, or from 50 to 224 grammes (from two to eight ounces) of stewed apples, from 123 to 163 grammes (from four and a half to six ounces) of veal, from 43 to 100 grammes (from two to four ounces) of eggs, and from 83 to 315 grammes (from three to 11 ounces) of bread. His daily allowance of wine was 400 grammes (14 ounces).

For the purpose of showing the relations between these figures and their values under ordinary circumstances some notes are subjoined on the conditions of assimilation in the normal state. In forming an opinion as to the assimilation of albumin it is to be kept in mind that with ordinary mixed, not specially selected, diet a loss of from 6 to 12 per cent. in the fæces is always to be expected.* As regards fat, a waste of from 10 to 15 per cent. of the fat contained in the food is considered as normal and a matter of course when the quantity of fat in the food is small, as, for instance, from 25 to 40 grammes per day. But when, as in this case, the average supply of fat is larger and rises to [illegible] grammes of daily [illegible] per day, then the foregoing percentage is much

---

* [illegible]

1. Pernicious anæmia is a special *form of chronic blood* poisoning—a toxæmia. 2. It is the result of a special infection of the digestive tract, especially of the mouth and stomach and probably, although to a less degree, of the intestine. 3. The chief source of the infection is through the mouth, from long-continued and *neglected cario-necrotic* conditions of teeth and sometimes possibly from stomatitis arising from other causes. 4. The usual effect of this infection is a chronic infective catarrh of the mouth and stomach which may in time lead to deeper seated changes, e g., ulcers *of the mouth and* tongue, chronic glossitis and atrophic changes in the tongue, and chronic gastritis with atrophy of gastric glands. 5. Evidences of the infectivity of the organisms of dental decay are overwhelming, and in suitable cases the infective nature of the resulting catarrh of stomach can also be demonstrated. 6. The infection is chiefly streptococcal and probably derives its special characters from being of a "mixed" character. 7. Such *infection* the more readily occurs if the stomach or intestine is already from any cause the seat of disease. 8 The gastric and intestinal irritation (sickness, retching, vomiting, looseness of bowels, and diarrhœa) so often noticed, and which I find to be even more common than is stated (being recorded in close on 80 per cent. of cases) is the local effect of this infective catarrh, while the excessive destruction of blood taking place in the portal area is the result of the action of the poisons in the blood. 9. The fever so commonly met with is not an accidental occurrence, the effect of weakness, but is a feature of the disease, a result of the infective process itself, and its variations correspond to variations in the activity of that process. 10. Such variations are common—from week to week, sometimes from day to day, in the progress of the disease, even when it is running a fairly progressive course. 11. In addition, however, the course of the disease towards the fatal termination is often marked by one—sometimes by two—periods of marked improvement, lasting, it may be, many months or a year or more, followed by relapses. This character of the disease I have come to regard as the result of a relative immunity, unfortunately only temporary in its nature, conferred by the disease itself—an immunity accelerated and greatly strengthened for a time by suitable medicinal treatment, notably by administration of arsenic. 12 The above conclusions suggest certain new considerations in regard to treatment, of which the chief are: (*a*) minute attention to the hygiene of the mouth and especially of the teeth, with the immediate removal of every source of infection there; (*b*) stricter antiseptic treatment of the stomach and intestine; and (*c*) antitoxic serum treatment with the view of antagonising within the blood itself the poisons absorbed into it.

III.—DENTAL, ORAL, AND GASTRIC CONDITIONS IN SEVEN CASES OF PERNICIOUS ANÆMIA.

That a disease so rare as pernicious anæmia should prove to be a chronic infective disease, still more that it should appear to have any connexion with a condition so common as cario-necrosis of the teeth, may well excite surprise. For the former conclusion my former observations had already prepared me, but for the latter I was quite unprepared, and its gradual development in my mind—for it has been very slow and gradual—may be best traced by giving a brief summary of the cases in the order in which they occurred. The fuller details will be reserved for the end of this paper.

CASE 1 (1888) —This was a case of pernicious anæmia in a man of 59 years of age. There was a history of "gastritis" six years previously. The origin of the illness was referred to a definite exposure to bad drains three years before, causing at the time sore-throat and diarrhœa, and followed by a constantly recurring inflamed condition of the throat and tongue and by increasing debility. The teeth were loose and the gums spongy. There were tender, inflamed sores under the tongue and chronic glossitis. Retching and vomiting were present in earlier stages of the illness, but in later stages they were absent. The blood showed 950,000 of red corpuscles, or 19 per cent., per cubic millimetre, and hæmoglobin 20 per cent. There were well-marked toxæmic attacks, marked by fever, sweatings, looseness of bowels, and intense urobilinuria. The post-mortem examination detected chronic and subacute gastritis of three years' duration, and typical pigment changes in the liver and kidneys. It was this case that first drew my attention to the mouth as a possible source of infection. The condition of the teeth and the gums I noted as a part of my routine examination, but it made no special impression on my mind. If I thought of it at all I put it down to weakness

CASE 2 (1894).—The patient was a man, aged 42 years, with a history of growing pallor for four years. The origin of his illness was referred by himself to a change of tooth-plate. He had a new set of upper teeth fixed in a gold plate, which tarnished and tasted "like pennies" and caused "acidity" from the first day he used them. Then followed progressive weakness, vomiting of food, nervous disturbances, numbness and tingling in hands and feet, loss of knee jerks, wasting of certain muscles, a toxæmic attack marked by delirium, constant vomiting, and general œdema. Under corrosive sublimate there was a rapid recovery in three months' time, and the patient remained well for two years. Then came a relapse, with sickness and biliousness, fever, and looseness of the bowels. The blood showed 1,800,000, or 36 per cent., of red corpuscles per cubic millimetre, and hæmoglobin 38 per cent. This case, striking as it was, failed to excite any special attention to the mouth or the teeth. I have no note of the condition of either. The absence of any note about the tongue may be taken as indicating that nothing special was observed in its condition. As regards, however, the previous condition of the teeth, the fact that already at the age of 38 years (four years before) he required a new set of false teeth for the upper jaw speaks more eloquently, perhaps, than words could do.

CASE 3 (1895).—This *was a case of pernicious anæmia.* The patient was a man, aged 60 years, whose previous health had been good. The origin of his illness dated from "influenza" two years before (in 1893), followed by another attack a year later (in 1894), and then by loss of appetite for both food and drink. After 1893 he constantly complained of a faint, weak feeling in the stomach. There was temporary improvement from December, 1894, to May, 1895. Between October, 1894, and May, 1895, the tongue was raw and tender "like raw liver," causing him intense pain. There were also toxæmic attacks and acute relapses of fever with disturbances of liver, also sickness and vomiting and gastric pain. The blood showed 1,860,000, or 37 per cent., red corpuscles per cubic millimetre and hæmoglobin 54 per cent. The duration of the illness was about two and a half years. No note as to the condition of the teeth had been taken when I saw him. I subsequently learned that he had bad teeth, with occasional neuralgia—seldom toothache. Latterly he would discover that a tooth was loose and could be drawn out without the slightest force or trouble.

CASE 4 (1896).—The patient, aged 56 years, suffered from pernicious anæmia. He was a country gentleman and was active and athletic. There was a history of increasing weakness, with intermittent periods of betterment, for two and a half years; specially marked for the previous three months. The tongue was soft, clean, moist, and not indented. The teeth were very bad, black, and decayed in both fangs and crowns. The stomach was dilated, with splashings and flatulence. There was no sickness, but uneasiness and discomfort. The patient had diarrhœa five or six times daily, with very offensive stools. There were nervous symptoms, numbness, tingling, loss of knee-jerks, and ataxia. The illness ended fatally. The blood showed 760,000, or 15 per cent., red corpuscles per cubic millimetre, and hæmoglobin 18 per cent. The duration of the illness was two and a half years.

It was this case that first directed my attention to the teeth. The case was a typical one in its mode of origin, showing steadily increasing weakness in a man previously strong and athletic, living a country open-air life, surrounded by every comfort, without exposure to any source of drain or sewer poisoning. What chiefly directed my attention to the teeth in this case was not, perhaps, so much that they were bad—although a blacker and worse mouthful of teeth I have seldom seen—as wonder that anyone in this patient's station of life and with his comforts and surroundings should have allowed his teeth to get into such a condition. Apart from the blood changes and their effects, which were very marked, the condition of the teeth was practically the only objective sign of disease that he presented. I could not believe that they could be the result of the disease; and the question arose in my mind, for the first time, whether they could have had anything to do with causing the disease. Locally, in the mouth, there was no obvious sign of disease, and except for a dilatation of the stomach with an ill-defined sense of discomfort there was nothing special to point to disorder of the stomach The only symptom of disorder of the digestive tract was the diarrhœa, which was marked by particularly offensive stools My suspicions might prove to be quite groundless, but I resolved henceforth to note the condition of the teeth in all cases coming under my notice

CASE 5 (1896) —This was a case of pernicious anæmia The patient was a clergyman, aged 51 years, whose previous health had been good, for he had never had any illness till the present time Its origin was undefined There was no history of drain poisoning, but there had been increasing weakness for 12 months, especially the last four months There was no history of indigestion, sickness, or vomiting, and the freedom from these symptoms continued, at most there was slight flatulence The tongue was clean, but not specially smooth, and with nothing abnormal Of the teeth, *two or three were exceedingly bad*, three being black rotten stumps in the lower jaw There was no diarrhœa Urobilinuria was present The patient made a temporary recovery but a relapse followed by death ensued The blood showed 1,230 000 or 24 per cent, red corpuscles per cubic millimetre and hæmoglobin 40 per cent The duration of the illness was two and three quarter years This case coming as it did within a fortnight of the previous one, served further to direct my attention to the teeth, for here also the teeth were the only diseased part of the organism apart from the blood changes and their effects There was no local trouble in the mouth, but the teeth were so bad that I remember stating that if the patient were not so weak I should like to have them all removed at once

CASE 6 (1898) —This was a case of pernicious anæmia in a man who had a history of indigestion and poor appetite and was aged 52 years The patient had been ill with anæmia six months before (in 1897) without sickness, but with irregularity of bowels, diarrhœa at times, and slight fever The tongue was clean but flabby The teeth were very bad and covered with tartar and sordes Three upper molars were gone, but the roots were left and one of them was loose and could be pulled out with the finger The breath was very bad, the digestion was very feeble and the bowels were irregularly loose Towards the end of the illness there was gastric pain on eating The case ended fatally The blood showed 1 390,000, or 27 per cent, red corpuscles per cubic millimetre, and hæmoglobin 34 per cent The duration of the illness was (?) nine months In this case there was a history of chronic indigestion very bad teeth, very feeble digestion, and later gastric pain and irregular looseness of bowels

The next case of interest to me in this relation that I met with was not one of pernicious anæmia but of subacute gastritis, caused and kept up by three suppurating teeth and permanently cured by removal of these teeth

CASE 7 (1898) —This was a case of subacute gastritis in a woman aged 62 years The patient suffered from severe intermittent sickness and gastric pain, necessitating the use of morphia, lasting eight months with loss of weight and increasing weakness Cancer was suspected, but on examination no sign of malignant disease was visible in the stomach, the abdomen, the rectum or the uterus Constant complaint was made of a bitter taste in the mouth nausea and loathing and distaste for all food The tongue was coated with a dirty moist fur The patient had false teeth both in the upper and the lower jaws The plates were scrupulously clean and the gums beneath the plates were perfectly healthy There were only three teeth in the jaws, and these were decayed there being suppuration around the roots with pus welling up on pressure There was no other sign of disease A provisional diagnosis was made of gastritis caused by continual swallowing of pus The stumps were ordered to be removed A week later the tongue was clean the sense of taste returned *for* the first time for eight months and there had been only one attack of gastric pain In another week there was a return of the sickness with vomiting and pain and slight fever The vomit obtained was free from *food*, it was watery, with rusty flakes consisting of mucus fibrin, catarrhal cells, leucocytes and blood, the whole being loaded with streptococcus and staphylococcus (pus) organisms and a few bacilli A diagnosis was made of infective gastric catarrh As a local antiseptic three grains *of* salicylic acid were given thrice daily and peptonised milk was also given and counter-irritation was applied There was complete cessation of all pain and a steady recovery *from* that time onward When the patient was first seen her weight was 9st 10lb, and a month later (after her illness) it was 9st 6lb Two months later it had increased to 10st 6lb She reported herself well and she has since remained well (after 15 months)

Up to this time my suspicions regarding the teeth were based on general grounds Knowing as I did how infective the organisms of dental caries were, such unhealthy teeth seemed to me to be *possible* sources of infection I had had no proof that infection from decayed suppurating teeth might be the direct cause of gastritis, nor did I know of any observations showing this This case was a particularly crucial one in this relation Had the teeth as a whole been very bad—e g, a number of rotten stumps interspersed with fairly good teeth, the condition one so often meets with both in private and still more in hospital practice—and had I had them all removed and replaced with good artificial teeth, I could *not* have been *sure* that the *resulting improvement* was due to removal of the teeth as sources of infection and not rather to improved appetite and better mastication As it was as regards new teeth no change was made, or, indeed, was necessary The only change made was the removal of the three suppurating teeth, which had, the patient said, never caused her any trouble and which indeed she regarded as "old friends whose loss she greatly deplored She said that "she had had them like that for 12 months or more '—her gastric trouble be it noted extending over about the same period of time I was able to demonstrate further in this case the infective nature of the gastric catarrh, the fluid vomited being loaded with pus organisms, three weeks after removal of the suppurating teeth

CASE 8 (1899) —This was a case of pernicious anæmia The patient was a man, aged 53 years, whose health up to June 1898 had been good There was a definite history of exposure for a period of some weeks to sewer gas He suffered from retching vomiting, and pain after food with intense salivation and gastrorrhœa The upper teeth were all absent except one in front which was dark, decayed, and loose in its socket Several molars and bicuspids were absent from the lower jaw He had worn tooth plates for the previous two years At the commencement of illness there were painful sores in the mouth under the tongue, which soreness as he said "seemed to spread down into the stomach and right through him" The blood showed 1 290 000, or 25 per cent, red corpuscles per cubic millimetre and hæmoglobin 24 per cent The vomited fluid was watery, with flakes of mucus and catarrhal cells, the whole being loaded with small cocci often in zooglœa like masses There were also bacilli and larger cocci but in fewer numbers A rapid temporary improvement was made under salicylic acid, but this was followed by a relapse marked by salivation, stomatitis occasional diarrhœa progressive weakness œdema acute epididymo orchitis and ultimately by death The duration of the illness was one and a half years

This case, coming so shortly after the observations made in Case 7, I regard as one of the most instructive which I have met with in respect not only of the history of its origin but also of its oral and gastric symptoms The illness dated from a definite exposure, lasting for a period of some weeks, to the *odours of a* cesspool close to the window where he worked, the smells from which were so bad that they often made him sick Among the first troubles he noticed were sores in the mouth, and his own description of his disease was that this soreness seemed to extend right through him from the mouth to the anus Then followed retching and salivation to a degree such as I had never before witnessed pints of fluid daily being brought up either directly from the mouth, or indirectly by vomiting from the stomach There was a history of dental trouble all the teeth in the upper jaw being absent with the exception of one which was markedly rotten and loose This, however, he valued despite its looseness and would not allow it to be removed Lastly there was the microscopic observation made on the vomited fluid which demonstrated the presence of *masses of* cocci The relation of events in his illness seemed thus to be in my mind 1 Previous dental trouble extending probably over many years (he had worn tooth plates for two years, but still retained decayed teeth) 2 A definite exposure to sewer gas infection which, either alone or in combination with preceding infection from the teeth set up both local infective trouble in the mouth (*sores* under the tongue with salivation and stomatitis) and gastro intestinal trouble (gastric infective catarrh with retching, vomiting, and pain). 3. The rapid onset of anæmia. Three months later the patient became so anæmic that he could not work and there was so much gastric trouble that cancer was suspected. 4. The subsequent history of the case—that of pernicious anæmia.

(*To be concluded.*)

EXCISION OF THE SPLEEN FOR INJURY.

BY O. ST. JOHN MOSES, M.B., C.M. EDIN.,
LATE CIVIL SURGEON, BACKERGUNGE, BENGAL.

ON Jan. 6th, 1899, a man was brought into the outdoor department of the Barisal Hospital, Bengal, by the police, whose report was to the effect that a quarrel had arisen between the patient and a neighbour, in the course of which they came to blows and the latter struck the former with a sharp-edged weapon (a *dao*) so as to wound him in the "stomach." My assistant surgeon (Babu Radha Nath Bose) on examining the patient at the time found that he had received a severe abdominal wound from which there was a dark congested-looking mass protruding, that considerable hæmorrhage had occurred, and that the patient's clothing had been stained, not only with blood, but also with mud, as though he had been working in the fields at the time when he received the injury. The patient was a well-built man, aged 45 years, by caste a Mahomedan, by occupation a cultivator, resident in the village of Nazirpur (police-station Gournadi). The symptoms of shock were well marked, for the man's face was pale, his lips were blanched and his hands and feet were cold; but he retained consciousness, there was no nausea or vomiting and there was no marked muscular relaxation. The pulse was comparatively feeble, but the heart-sounds were distinctly audible and apparently not much altered from the normal. On the left side of the abdomen, in the hypochondriac region and in the angle formed by the costal cartilage of the tenth rib and the left linea semilunaris, there was an incised wound, two and a half inches in length and three-quarters of an inch in width, and penetrating the whole thickness of the abdominal wall. The direction of the wound was from above downwards and slightly outwards so that the upper end, also somewhat wider, approximated more towards the middle line than did the lower end. Protruding outwards between the lips of the wound was a dark congested mass, a portion of the spleen. The lips of the wound had contracted tightly round the base of the projecting portion so as to prevent the return of venous blood. Moreover the capsule of the organ was incised to the extent of one and a half inches and the splenic pulp was bulging through this opening. Considering, then, the circumstances of the case, the fact that the injury had been inflicted some little time previously, and taking into account that the patient had been brought a considerable distance and that his wound had been exposed to septic influences, such, for instance, as contact with dirty clothing, I feared the effects of septic processes more than those of shock or hæmorrhage or other conditions. Thus I decided that it would be unwise to return to the abdominal cavity a portion of viscus which had been exposed so long and under such circumstances, especially as it seemed to me just possible that the peritoneal cavity might as yet be free from infection since the tight sphincter arrangement of the wound prevented the inflow of any fluid from the external surface. Of course there was the chance that the weapon which inflicted the injury had also carried septic infection into the peritoneal cavity, but even though such were the case it did not seem prudent to add to the dangers by wilfully returning a piece of septic spleen whose vitality was already lowered and whose substance would favour the growth of septic organisms in the patient's present condition. Yet at the same time I was unable to satisfy myself that the muscular contraction at the seat of injury had been so complete as to have excluded all chance of infective material having passed from the wounded surface of the organ to the portion still within the abdomen. The possibility of such a spread impressed itself the more upon me when I considered the dorsal decubitus of the patient and the consequent action of gravity. Under the circumstances, therefore, I looked upon the entire spleen as an infected organ, and I satisfied myself that its complete removal would minimise the risks of the patient.

Operation.—My first step was to administer to the patient half-drachm doses of compound spirit of ether and aromatic spirit of ammonia by way of stimulant. I had no fear of hæmorrhage at present, as the capillaries on the wounded surface of the abdominal wall had long ere this ceased to bleed, whereas the hæmorrhage from the injured organ and its capsule were held in control by the muscular edges of the wound. My next care was to wash the wound and the surrounding parts with the greatest precautions, and for this purpose I used by preference a solution of carbolic acid in the first instance of the strength of one part of the acid in 50 of water. This antiseptic substance penetrates more deeply into the tissues and thus finds its way into crevices far more readily than does the perchloride of mercury. Next, taking a long strip of lint about two inches wide and wringing it out of the antiseptic solution, I sprinkled it over with a mixture of equal parts of iodoform and boric acid and packed it round the base of the protruding tongue of spleen so as to prevent the ingress of any fluid into the peritoneal cavity. At this stage chloroform was administered and when the patient was thoroughly under the influence of the anæsthetic I secured the protruding mass by means of an ordinary hæmorrhoidal clamp such as that devised by Smith. This served a double purpose, for it acted as a ligature, preventing the inflow of any blood from this part of the organ and it also kept the projecting portion from slipping in when I took the next step in the operation. This consisted in extending the abdominal wound downwards for a convenient distance; in the present case one inch sufficed. In doing this, however, I adopted the plan of cutting at first through skin, fasciæ, and muscular layers only, then arresting the hæmorrhage completely, and finally extending the peritoneal opening. The spleen was quite isolated and its attachments, especially the gastro splenic omentum, were lax, and this allowed of my lifting the whole organ out and bringing the pedicle to the surface-level. I carefully avoided either pressing upon or pulling the spleen more than was absolutely necessary, so that I ran no risk of either squeezing infected material inwards or of rupturing the vessels at the hilum. I next proceeded to ligature the pedicle and for this purpose I used stout chromicised carbolised catgut, believing that the chromicised material does not so readily absorb septic matter as ordinary catgut or silk, which latter is also apt to become too loose as the enclosed portions contract. I applied double ligatures and before removing the parts external to the outer ligature I passed two sharp-pointed probes through the substance of the pedicle between the two ligatures. The probes were at right angles to one another; their sharp points were protected by means of two pieces of cork, their ends rested upon the surface of the abdomen, and their function was to support the stump which would remain after removal of the main body of the organ. Having done this I cut away the entire spleen external to the outer ligature. The remaining stump I treated exactly like the stump of the uterus in a Porro's operation—that is, at the wound which I closed round it. The wound was then dressed in the ordinary way with perchloride of iron. During the whole operation the greatest care was taken to prevent any fluid from passing into the peritoneal cavity; no appliance was introduced into that cavity, and by protecting the abdominal opening with a piece of gauze wrung out of carbolic lotion any air that passed into the peritoneal cavity was, as it were, filtered through an antiseptic medium. The spleen weighed 12½ ounces, and measured six inches in length, four and a half inches in breadth, and one and a half inches in thickness. In colour the organ was dark. It had, moreover, a slight constriction round the part that had been held by the abdominal wound.

After treatment.—The patient was kept at absolute rest and for the first 48 hours was fed entirely on milk. Pills containing each a quarter of a grain of the extract of opium and the same quantity of the extract of belladonna were administered at intervals in order to keep the patient at perfect rest and, by producing an artificial constipation, to avoid all straining efforts. At the end of 48 hours I dressed the wound with very great antiseptic precautions, the process being repeated every second day thereafter. On the eighth day after the operation (Jan 14th) the healing process had advanced so far as to allow of the removal of the probes, and a fortnight after the operation (Jan. 20th) the wound had completely healed up. On the following day I permitted the patient to be removed to the Barisal jail as a warrant had been issued for his arrest. I continued, however, to keep the man under observation in the jail hospital, and after an interval of some days I transferred him to the "convalescent gang," where he was kept on special diet and being an 'under trial' prisoner he had no work to do. On Feb. 3rd he was able to appear for trial in court. During the whole period of convalescence the patient's temperature never rose more than one degree above the normal; his pulse gradually returned to a healthy condition, and his appetite remained good. The recovery made by the patient was remarkably speedy, and the last report I had of him was in a letter dated Nov. 16th, 1899, which stated that he was in good health and able to attend to his ordinary occupation as in former times.

I may add that no vomiting occurred either during or after the operation and that no hæmorrhage or other complication took place during the period of recovery. An examination of the patient's blood made after the operation revealed no very marked condition, but having had no occasion to make such an investigation before the removal of the spleen I am unable to make any comparative statements. From the somewhat complicated physiological functions which the spleen discharges during health as a member of the hæmopoietic system, we should be led to expect important changes in that system and especially in the blood, after total removal of the organ in question. Such changes have from time to time been observed. Thus considering that the chief functions which the spleen discharges in the physiology of the human system are concerned with the production of white blood corpuscles, the breaking down of the red blood corpuscles (hæmolysis) and the metabolism of proteid substances, the breaking down of hæmoglobin—the change we should most of all look for after removal of such a body is an alteration in the relative proportion between white and red corpuscles in the blood. This has been noticed by several observers. Moreover, it frequently happens that the lymphatic glands take on a condition of hypertrophy to compensate as it were for the loss of the spleen. These lymphatic glands being engaged in the production of the white corpuscles of the blood their tendency is to increase in size and in activity and to correct the alterations in the blood often to the extent of making them inappreciable. Among others Czerny and Kocher have noticed enlargement of the lymphatic glands under such conditions. In the case that was under my care a close search revealed a single superficial lymphatic gland belonging to the femoral group on the left side swollen to the size of a small bean. It was situated a little below and to the inner side of the saphenous opening; slight pressure applied to the long saphenous vein over the lower margin of that opening in the fascia lata was sufficient to make the vessel stand out external to the swollen gland. Besides the swelling could not be traced to any other cause; it was not present at the time of the operation but appeared on the third day after and it gradually disappeared in the course of a week without the aid of any external application.

The operation of extirpation of the spleen or splenectomy as it is called, has been performed for many causes and with a varied degree of success. Leucocythæmia, chronic congestion of the spleen, albuminoid degeneration, syphilitic enlargement, simple and malarial hypertrophy of the organ, floating spleen, hydatid disease, cystic spleen, sarcoma, abscess, rupture, and wounds constitute the list of conditions for which the operation has been attempted. In leucocythæmia, chronic congestion, albuminoid degeneration, and syphilitic enlargement the results obtained from this operation have shown so high a mortality as to render this mode of treatment unjustifiable under the circumstances. In cases of simple and malarial enlargement and of floating spleen the results have been considerably better. Vulpius of Heidelberg in the tables of cases he has collected quotes two instances of ruptured spleen, both of which ended fatally. The operation is to be considered as one which is exceedingly severe which should only be undertaken when the surgeon is perfectly satisfied that it is the course of treatment which of all others under the prevailing circumstances is calculated to diminish the risks to be borne by the patient and when the operator is quite certain regarding the efficacy of his antiseptic arrangements. Besides the dangers common to all forms of laparotomy, especially infection of the peritoneum and its results, the great fear in this particular operation is that of hæmorrhage from the vessels at the hilum of the spleen. In the case which I have described the risks of such an accident were minimised to a great extent by the mode of procedure which I adopted.

Edinburgh.

THE PATHOLOGY AND TREATMENT OF APPENDICITIS.[1]

BY C. B. LOCKWOOD, F.R.C.S. ENG.,

ASSISTANT SURGEON AND LECTURER ON SURGICAL AND APPLIED ANATOMY, ST. BARTHOLOMEW'S HOSPITAL.

IN the discussion which took place recently before the Medical Society of London on the Prognosis of Appendicitis and which was introduced by Dr. H. A. Caley this observer and some of those who spoke made use of clinical statistics to a large extent. This method of inquiry is obviously of value, but it has not hitherto carried conviction to the minds of physicians and surgeons. The reason for this is simple. Taking the 99 cases of simple appendicitis and perityphlitis, on which Dr. Caley's remarks had been based, in which the patients were said to have recovered it is reasonable to ask how this is known to be true. A certain proportion of them must have had concretions in the appendix. The attack may have subsided, but the patients had not recovered and the appendicitis was sure to recur. It would be just as reasonable to say that a patient with stone in the bladder had recovered because after rest in bed an attack of cystitis had subsided. Without doubt some of the 99 cases relapsed and the patients went to other hospitals and were there included amongst the severe cases with perforation, gangrene, or septic peritonitis. I venture to think that appendicitis cannot be correctly prognosed until it is possible to infer from the clinical symptoms the pathological changes proceeding within the appendix. I do not intend to discuss the nomenclature of diseases of the vermiform appendix; much confusion prevails and the classification adopted by many authors is illogical. When inflammation originates in the vermiform appendix I intend to call it appendicitis and to add terms to indicate the *effects* which the disease has produced, such as ulceration, perforation, gangrene, the various inflammations of the peritoneum, of the broad ligament of the uterus, of the portal vein, and so forth. The remarks which follow are based upon the histological examination of 53 cases of appendicitis ranging from the slightest to the most acute. The specimens have been obtained from cases which I myself had operated upon and of which I know the histories.

The first group of cases is that in which suppuration was absent. Some of these cases come under the head of "appendicular colic." In these so far as is known no clear attack of appendicitis has ever occurred. They were characterised by slight *tenderness on pressure* over some part of the iliac fossa, by *disorders of digestion*, and by occasional attacks of transient pain not infrequently mistaken for renal colic.

[Regarding the normal anatomy of the appendix Mr. Lockwood directed special attention to the lymphoid follicles and the lymphatic system of the appendix. The continuity of the submucous and subperitoneal tissues through numerous gaps (hiatus muscularis) in the muscular coats was pointed out and the paths by which inflammatory and infective inflammations of the mucosa spread to the peritoneum were demonstrated by lantern slides.]

In a case of appendicular colic such as was described by Talamon a healthy young woman suffered for 18 months from abdominal pains. During the last six months she had been unable to follow her occupation. The pain was referred to the right side of the abdomen and to the right iliac fossa. It had been diagnosed as being caused by colic. The appendix was removed. To the naked eye it appeared normal. Microscopical section, however, showed the lumen to be filled with epithelium, mucus, granules, and crystalline bodies, and crowded with diplococci, small ovoid bacilli single and in pairs, small clumps of staphylococci, and streptococci in chains from four to six, and some long slender bacilli. In the microphotograph the lumen of the appendix is seen to be crowded with all these various bacteria have penetrated for perhaps half a millimetre into its substance. We might be reluctant to advise the removal of the appendix for a disease designated "appendicular colic." Such a designation conveys but little idea of danger. But few would hesitate to remove an appendix the mucosa of which was ulcerated and invaded by bacteria.

---

[1] An abstract of a paper read [illegible] before the Medical Society of London [illegible]

[2] The Lancet, Dec. 2nd, 1899, p. [illegible]

Amongst the cases which have been included under the term "catarrhal appendicitis" until the result of the histological examination has been ascertained the following has been considered a typical case. A young man, aged 29 years, had his first attack of appendicitis at the age of 19 years. During the next 10 years he had so many attacks that he could not recall their number. They usually confined him to bed for a day or two and prevented him from going to business. Perhaps an operation had been deferred because he suffered from mitral disease. The appendix was removed in the usual way and was not adherent. It was engorged with blood and felt very hard. It was constricted about three-quarters of an inch from the intestinal end. The micro-photograph shows the mucosa to be ulcerated and the lumen to be filled with granules, crystalline bodies, shreds of organic matter, irregular pieces of semi-transparent substance, and quantities of bacteria. These include many morphological varieties, cocci, diplococci, short ovoid bacilli single and in pairs, long slender bacilli, short thick bacilli with rounded ends, long thick bacilli, leptothrix, spores, and spore-bearing bacilli. Many of the tubular glands had shed their epithelium which had been replaced by plugs of bacteria projecting from the lumen. In some places these bacteria were penetrating the lymph canalicular system of the mucosa. The term "catarrhal appendicitis" does not perhaps convey to the mind a very clear sense of impending danger, but no one who is aware of the pathological state of such an appendix as this would hesitate for a minute in advising its removal.

Of the other pathological conditions associated with clinical signs of appendicitis I will take the effects of stenosis first. The appendix of a young woman who had had four attacks of appendicitis was removed. During the attacks the temperature rose. She had pain in the right iliac fossa, which was so severe as to cause collapse, there was constipation but no vomiting. Betwixt the last two attacks pressure in the iliac fossa was painful so that it was obvious that although appendicitis had subsided it had not got well. The appendix was not adherent, was nearly four inches long and constricted from the cæcum. A micro-photograph of the constricted part shows the mucosa beyond the constriction to possess an epithelial lining. The lumen contains pus full of streptococci. It is hardly necessary to point out the danger of this condition, but to render it clearer micro-photographs of another case were referred to. A man had had six attacks of appendicitis and was advised to have his appendix removed. The operation was deferred until after his wife had been confined. When next seen he had no signs whatever of appendicitis but was obviously suffering from hepatic abscess. An attempt was made to discover this abscess from behind but without success. A second attempt was made in front. No abscess could be discovered, but inflamed glands were felt about the cæcum. The appendix was therefore removed. The micro-photograph showed that the interior contains pus full of streptococci with a few bacteria of other types. The lymph on the surface of the appendix was also full of streptococci. The patient survived this operation, but ultimately he died from portal pyæmia with a number of abscesses in the liver. The delay in this case is evidently a matter for the keenest regret, and it would never have been permitted had the pathological condition of the appendix been accurately diagnosed.

[Some of the effects of ulceration of the mucosa and subsequent infection of the appendicular wall were next illustrated by Mr. Lockwood. Also the dangers of fæcal concretion. Fæcal concretions were shown to be bacterial masses, a point which, strangely enough, had not been demonstrated by any investigator. He then continued:—]

I regret that I have not time to demonstrate by specimens the various steps in the formation of fæcal concretion. These specimens show that fæcal concretions are always associated with general ulceration of the mucosa; that the concretion was not necessarily the cause of the ulceration; and that the concretion and the ulceration both owed their origin to the same cause, bacterial accumulation within the appendix. The presence of concretion in the appendix is evidence of extensive ulceration of the mucosa and bacterial invasion. A large concretion is in itself a mechanical peril when, owing to the application of cold to the surface of the body, the appendix becomes engorged. It may cause a perforation of the appendix in its vicinity or gangrene of the part beyond. If it be true that many of the cases of appendicitis which are said to have recovered as a matter of fact contain concretions it is easy to imagine their peril.

Of the so-called process of natural cure the accounts given by authors are fanciful. It is impossible to say when the so-called process of natural cure has been achieved. The appendix had been removed from a man who had had at least 20 attacks of appendicitis. He had twice been in large London hospitals, once under a surgeon and once under a physician. As they sent him out again without operation it is reasonable to suppose that they anticipated that the natural process of cure would eventually take place. The appendix was removed. A histological examination showed that the mucosa had been destroyed by ulceration and that the lumen was occupied by a concretion which seemed calculated to prevent any supposititious natural cure from taking place. An appendix which has once been inflamed may inflame again after long intervals. An appendix was recently removed for repeated and violent attacks of appendicitis which had recurred after a period of quiescence of nine years. In another case the patient had a violent attack of appendicitis, then an interval of 15 years of quiescence followed by another violent attack, after which the appendix was removed. It does not seem reasonable to lay down rules as to how many attacks should be suffered before the appendix is removed. I am inclined to wait for some time after the first attack of non-suppurative appendicitis to see what supervenes. But on several occasions the appendix has been removed after the first attack because it was still painful and could be felt. Under the circumstances the general health of the patient is seldom good and the functions of the alimentary tract are improperly performed, indigestion, flatulence, constipation, and diarrhœa being frequent accompaniments. After a second attack of non-suppurative appendicitis most patients prefer to part with an organ which appears to be of no physiological importance and an actual source of danger.

As to the question of diagnosis, it is usually possible to say that the appendix is inflamed, but hitherto the histology of appendicitis has hardly been sufficiently investigated for anybody to surmise with accuracy the actual pathological state of the appendix. The usual sequence of events, as shown by the histological examination of the 53 specimens, is destruction of the epithelial lining of the lumen, ulceration of the mucosa, bacterial invasion of the mucosa and submucosa, and extension of the inflammation through the muscular gaps to the peritoneum. This process may be complicated by the formation of cicatricial strictures, by inflammatory obliteration of the whole lumen after removal of the mucosa, by the presence of fæcal concretions, by perforation, by gangrene, by inflammation of the appendicular lymphatics, and by portal pyæmia. It is also important to note that, as Clado was the first to point out, the inflammation in females not infrequently spreads along the lymphatics to the right broad ligament of the uterus, so that appendicitis is sometimes mistaken for inflammation of the ovary or Fallopian tube. In three cases of this kind operations have been performed. In addition it is important to observe that appendicitis sometimes occurs as a complication of other diseases. Primary tuberculosis of the appendix is probably a rare disease; although every specimen has been carefully examined for tubercle it has only once been discovered. But on one occasion in operating for the removal of an inflamed appendix general tuberculosis of the peritoneum was discovered, the inflammation of the appendix being a complication of that disease. In another case of appendicitis a hard mass was discovered at the base of the appendix. When a portion of this was submitted to histological examination it was found to be cancerous. The cancer, which involved the ileo-cæcal valve, was removed and the intestine was united by circular enterorraphy. The patient recovered but ultimately died from a recurrence of the cancer in the pelvis. As regards cases of appendicitis in which perforation or gangrene has occurred there can be little doubt as to the propriety of evacuating and draining the abscess as soon as diagnosis can be effected. The cases show that the safety of the patient depends mainly upon the stage at which the operation is performed and the position which the appendix occupies. When the appendix is beneath the cæcum and in the iliac fossa the chances of the abscess being localised are fair; likewise when the appendix lies to the outer side of the cæcum and colon.

But, in females especially, the appendix often hangs over the brim of the pelvis into Douglas's pouch; when such an appendix perforates or becomes gangrenous the danger is vastly increased. Moreover, collections of pus at the bottom of Douglas's pouch are most difficult to drain.

As regards the operation I advocate the oblique incision parallel to the outer half of Poupart's ligament because it can be extended to reach an appendix which lies outside the cæcum, or which is adherent within the pelvis. The wound seldom exceeds three inches in length; such a length as two inches or two and a half inches is very common. The layers of the abdominal wall are split and not cut across. In non suppurative cases the appendix may be most difficult to discover. It may be laid down as an axiom that the organ is never absent except as the result of disease. Cases were mentioned in which the organ has only been discovered with the greatest difficulty because it was hidden away in either the subcæcal or the ileo-cæcal retro peritoneal fossa. Doubtless surgeons who have failed to find the appendix have not infrequently been deceived by this abnormality. In cases complicated with suppuration and peritonitis a determined endeavour should be made to remove the appendix. It is worth while to run considerable risks rather than to leave behind an appendix which is profoundly septic and which may contain concretions. In some cases in which the abscess has merely been opened and drained and the appendix has been left behind subsequent attacks of appendicitis have been known to occur. In others a septic sinus has persisted requiring a formidable and often fatal operation for the removal of the appendix. In one such fatal case the sinus led to a perforated appendix which contained a large concretion. Nevertheless the patient's condition sometimes forbids an attempt to remove the appendix. A case of this kind was under observation in which the original appendicular abscess had been followed at intervals by three others of the most formidable and dangerous type. As regards the closure of the wounds after the removal of the appendix in cases without suppuration it has been found inadvisable to insert buried sutures of silk, because infection is likely to occur when the lumen of the appendix is cut across. Good results have been obtained with a single row or fishing-gut sutures.

Operations for the removal of the appendix vary greatly in their gravity. The simple operation is comparable to the radical cure of non-strangulated inguinal hernia. But occasionally after violent appendicitis the most formidable adhesions are met with and they may test all the courage and dexterity of the operator before they are overcome. In my own operations for the removal of the vermiform appendix in which suppuration is absent the patients recover more quickly since they lie upon their side and are quickly put on solid food. In cases of appendicitis with perforation or gangrene and acute abscess the after-treatment requires the greatest skill and watchfulness.

DEATHS UNDER CHLOROFORM.

By JAMES EDMUNDS, M.D., M.R.C.P. LOND., &c.,

MEDICAL OFFICER OF HEALTH AND PUBLIC ANALYST FOR ST. JAMES'S; CONSULTING PHYSICIAN, LONDON TEMPERANCE HOSPITAL.

MANY of the readers of THE LANCET will have perused with much interest the remarks by Dr. Clayton Lane, Lieutenant I.M.S., on Deaths under Chloroform.[1] We must all agree with Dr. Clayton Lane that chloroform cannot be given with safety by any mere mechanical means, and that a man may be killed as effectively with chloroform out of a Krohne inhaler as out of any other inhaler that is capable of inducing anæsthesia. In fact, the best inhaler cannot supply the administrator with sense or with fingers. All that the inhaler can do is to become subservient truly and promptly to the highest order of professional intelligence. It can never read out for us the significance of the phenomena which occur in the progression of an anæsthesia, nor can it ever supply the administrator with skill or alertness.

Some comment upon Dr. Clayton Lane's letter has since appeared from Mr. C. H. Whiteford.[2] Unfortunately Mr. Whiteford does not state whether he still adheres to the rule-of-thumb method of administration or aims at scientific dosage. In the former case he offers us no basis for discussion. If the latter be Mr. Whiteford's aim, what we ask of him is to say whether he can show us any method of measured dosage other than the volumetric administration of air charged with chloroform vapour; and whether he can show us any apparatus by which precise and registrable dosage can be secured otherwise than by means of the improved Krohne inhaler.

To save wastage in chloroform, to save the operator's time, even to save the surgeons and nurses from being chloroformed almost as fast as the patient, are objects negligible in comparison with the conscientious fulfilment of the trust which is accepted by us when the patient submits himself to an anæsthesia. Under such a trust the administrator is bound by the most sacred ties of professional honour to see that his patient is anæsthetised with as much provision for a safe recovery as the administrator would wish for himself were he the patient. More than this cannot be asked for by the patient—less cannot be rendered by the administrator. There lie on my table newspaper reports of 83 inquests upon persons killed by anæsthetics in England in the year 1899. Of these, 68 were killed before the operation commenced. We know the inducements to have as few inquests as possible in such deaths, and we know also the inducements which lead to a suppression of the reports of such inquests. Reading between the lines it may fairly be estimated that these 83 inquests represent some 200 persons killed by anæsthetics in England during the year 1899. Can we, as a great and responsible profession, remain at rest in face of these facts? I think not. If that be so, in what direction are we to look for the remedy?

I submit that in the administration of chloroform what we must look for is the same precision of dosage as that which we ensure when we inject morphia or strychnia. Dispensers there are who could measure out a milligramme of strychnia on the end of a knife by means of the eye more closely than others could weigh it. The same is the case with 20 milligrammes of morphia. But we insist upon our hypodermic syringes being graduated, we insist upon our solutions being of a strength defined by the balance and the burette, and we do not allow pharmaceutical geniuses to play at "heads or tails" with the lives of our patients by guessing out strychnia on the end of a knife. That chloroform in vapour is a powerful poison is demonstrated by the above-mentioned deaths. Nevertheless, chloroform is, perhaps, the most beneficent of all drugs, and in order to be made safe it only needs to be administered with precision as to its dosage and not by rule-of-thumb methods, such as geniuses believe that they can safely practise. A true volumetric dosage of the vapour can now be obtained by means of the improved Krohne inhaler; it is therefore practicable always to administer anæsthetics with the same precision and security as we have long ensured for the administration of morphia or strychnia. Some of us remember the old school who used to scorn the clinical thermometer as a histrionic dodge, or as only good enough for those whose tactile sensibility was not sufficiently cultivated to recognise accurately the gradations of a patient's temperature. Yet now we all know that the clinical thermometer enables any nurse to define the patient's temperature at any moment to a tenth of a degree and that it is indispensable in clinical medicine. The same cast-iron pachydermatousness in our methods of administering anæsthetics now has to be vanquished if we are to make any true scientific progress towards bestowing upon our patients the blessings of a safe anæsthesia. Geniuses who have acquired the habit of slopping chloroform about by the ounce, and who only kill a patient now and then, will of course be disgusted at having to acquire methods of order and precision such as will ensure a comfortable and safe anæsthesia with one tenth of the chloroform now used. The volumetric dosage of anæsthetic vapours will in fact be received in the same way as the stethoscope and the clinical thermometer were sometimes received. But the volumetric dosage of anæsthetic vapours will come to stay and there is only one instrument now before us by which it can be accomplished conveniently in clinical work. That instrument is the improved Krohne inhaler—used as I have described.[3]

The deaths with cyanosis, as described by Dr. Clayton Lane, are undoubtedly due to asphyxia, more or less pure. These deaths are caused by the inspiration of air surcharged with chloroform vapour. Spasma glottidis, resistance, general *rigidity or struggling*, spasm of the respiratory muscles and diaphragm, together with spasm of the myocardium,—these are all provoked in various degrees, sequences, and combinations by the inspiration of surcharged air. The patients die from asphyxia more or less complicated by an angina which affects the heart much as cramp affects the calf of the leg. If the patients do not die suddenly as above and the chloroform be pushed there comes a paralytic relaxation of the glottis—as in drowning—and this is followed by further deep inspirations of surcharged air, just as, in some fatal cases of drowning, water and mud are drawn into the lungs. It is well known to practical men who have seen much of drowning cases that there are some cases brought to bank with the heart still beating and the chest movements still going, but which cannot be resuscitated, work as hard as we may at artificial respiration. They are these particular cases, and at the necropsy mud and water are found in the bronchial tubes. When got out of the water these cases can be distinguished by the fact that, though still breathing, foam issues from the mouth and nose. In my experience those cases are rarely resuscitated. Now in chloroform poisoning, after the paralytic relaxation of the glottis, the surcharged air re-enters the bronchi, surcharges afresh the pulmo-cardiac blood, and fills up the recesses of the air passages. Here the end organs of the whole system of respiratory nerves are poisoned by direct local soakage, while the surcharged pulmonary blood, passing on successively through the left chambers of the heart, poisons the myocardium and its local nerves in the same way. All this may be the work of half a minute in cases where chloroform is "pushed" after resistance has been provoked. If time had been given for the diffusion throughout the system of the chloroform ingested it would not even have produced anæsthesia. But it kills because it surcharges the local blood of the lungs and heart. It is not the total quantity ingested, it is the local surcharge—the concentrated action. A minim of oil of vitriol diffused through a wineglassful of water is drunk as a pleasant beverage—a minim of oil of vitriol dropped into the glottis is fatal. Then, as the lungs have had their air passages re-filled with surcharged air, the local poisoning goes on long after the inhaler has been removed, and the blood current through the chambers of the heart continues to be surcharged long enough to kill. Snow showed that 18 minims in the blood of an average man spell full surgical anæsthesia and that 32 minims spell death. But it is probable that four minims injected into the pulmonary vein would *kill* the heart nerves irretrievably. Powerfully absorbent must be the two successive chambers of the heart with all their complications of surface, in relation to blood which that organ has to receive from the lungs and to transmit under pressure to the general system. The experiment is one that could easily be tried at any slaughter-house or knacker's yard. What we want to know is what percentage of vapour-volume of chloroform serves to kill the animal heart beyond resuscitation. Waller has shown us that below 5 per cent. vapour-volume of chloroform in air arrests absolutely the function of a *nerve*, but *not* so as to prevent resuscitation. 6 per cent. *kills* the nerve. Now four minims of liquid chloroform may be regarded as four cubic inches of chloroform vapour. For a 6 per cent charge this four cubic inches of chloroform vapour would saturate the entire mass of the pulmo-cardiac blood and myocardium tissues. Hence these chloroform cases, like those particular drowning cases, are irretrievable by artificial respiration. The myocardium has been killed.

---

[1] Vide THE LANCET, Jan. 13th, 1900, p. 132.

[2] THE LANCET, Jan. 20th, 1900, p. 197.

[3] THE LANCET, Sept. [illegible]th (p. 72[illegible]) and Oct. [illegible]th, 1899 (p. 1205).

Referring to the injection of chloroform into the blood-vessels I am not unmindful of the fact that this was done under the Hyderabad Commission. But the Hyderabad report on that point is badly given and the results are inconclusive. Moreover, those injections were made into the jugular vein after the vein had been tied. Now, tying the jugular vein would stop the current through that vein, and it is not safe to surmise as to how much of that chloroform arrived in the heart or how long it required for such chloroform to arrive. Again, such chloroform as did arrive in the heart would go into its right side. Now, the right heart has always been accustomed to contact with blood charged with carbon dioxide, whereas the left heart has always contained pure oxygenated blood. The result, therefore, of the contact of chloroform with the different sides of the heart may be as different as the results of the presence of urine in the urinary bladder or in the peritoneum.

In using the improved Krohne inhaler it can be demonstrated that a full manual compression of the bellows projects four cubic inches of air saturated with chloroform vapour into the mask, which I have called the mixing-box. Taking this as giving *one* cubic inch of chloroform vapour, and assuming that the on-coming inspiration draws 25 cubic inches of air through the mixing-box, we have 1 in 25, or 4 per cent., for the vapour volume of chloroform in the *inspired air. If one full manual compression be given into* the ebb tide of each expiration (as described in my letters in THE LANCET of Sept. 30th (p. 922) and Oct. 28th (p. 1205), 1899) it follows that in *one minute* the patient will have received the vapour of some 20 minims of liquid chloroform into his lungs. Some of this 20 minims will have been exhaled by the lungs and skin, and as it requires 18 minims in the blood to induce full surgical anæsthesia this generalised effect will not be reached. But the ingested chloroform is probably a lethal dose by reason of the want of time for diffusion through the general system and the local *surcharging of the pulmo cardiac blood. For that reason a* much smaller injection for each inspiration is directed, and from the commencement of the administration to the induction of full surgical anæsthesia about six minutes is best as the least period.

The perfectly safe exhibition of chloroform is to be attained by beginning with small volumes of chloroform air for each inspiration, such as provoke neither cough nor resistance — certainly no spasm of the glottis. Here I differ somewhat from the text of the directions given by Dr. Clayton Lane, inasmuch as while I watch closely the phenomena of the anæsthesia I also cause *myself to know* where I am by regulation of the amount of chloroformed air injected for each inspiration. I thus use the two guides—observation and dead-reckoning—and I make the feather-indicator my index for the respiratory currents.

Manchester square, W.

THE USE AND ABUSE OF PRESERVATIVES.

BY SAMUEL RIDEAL, D.SC. LOND., F.I.C.

THERE are two or three points arising out of the recent papers which have appeared in THE LANCET which some experiments of mine, conducted during the last six months, seem to throw some light upon. When I was fortunate enough to secure the coöperation of Mr A. G. R. Foulerton at the end of 1898 for investigating this problem in my laboratory I realised that it was of a twofold character, and in the paper published in *Public Health* in May last by us we expressed our opinions (1) as to the quantities of preservatives necessary for preserving milk, and (2) the possibility of such quantities having injurious effects upon the consumer. In that paper we promised to extend our investigations, and as circumstances arose which necessitated our working in separate laboratories Mr. Foulerton continued the investigation into the second branch of the subject whilst I have recently confined my attention to the former. At the same time I should like to take this opportunity of saying that I fully agree with Mr. Foulerton in the conclusions which he has drawn in the very able papers published in THE LANCET of Nov. 25th (p. 1427) and Dec. 9th (p. 1577), 1899.

A good deal of the work which has recently been done on this subject has assumed the possibility of comparatively large quantities of preservative material being present in the food-supply, and there seems to be some hesitation in accepting the proposition which Mr. Foulerton and myself advanced in the paper above referred to—viz., that 1 part in 2000 of boric acid mixture and 1 in 50,000 of formaldehyde were quantities of preservatives sufficient for keeping milk sweet for a period of 24 hours even in warm weather. It is well known that at the present time these quantities are frequently exceeded, but I have been unable to find any experiments on a sufficiently large scale to warrant my believing that the milk trade necessitates higher quantities of these preservatives being added. I am assuming that the *Departmental Committee* at present dealing with this question will make it compulsory for the presence of any preservative in milk to be declared at the time of purchase, as I think that there is now a consensus of opinion that it is highly desirable that in special cases, such as in the case of invalids, it should be possible for the consumer to obtain a milk free from preservative, and that in all cases it is only fair that the consumer should be aware of the preservative if present. The views of Mr. Foulerton and myself as to the effect upon the health of adults and children of the above quantities of preservatives have already been stated in the paper referred to, and I need not go further into this matter, but the advisability of allowing greater amounts of preservatives than those mentioned to be present in "declared" milk is determined by the question whether the larger quantities are necessary for trade purposes. This point, of course, depends largely upon what is understood as "sour milk" by the consumer and this must obviously depend upon the acidity of the milk expressed in terms of lactic acid. In the following table I summarise the results obtained in a series of experiments undertaken to ascertain this point. Quantities of fresh milk containing (1) 1 in 2000 of boric acid, (2) 1 in 50,000 of formaldehyde, and (3) a control, were measured into balloon flasks and loosely plugged with cotton-wool. These sets were then incubated at the following temperatures: 13°C., 18°C., and 24°C. (as representing approximately winter, medium, and summer temperatures); and 25 cubic centimetres were taken out from each and titrated every few hours with decinormal soda, using phenol-phthalein as an indicator, the total acidity being calculated to lactic acid (one cubic centimetre N/10 soda = 0·009 gramme of lactic acid). The original milk at starting required five cubic centimetres N/10 soda per 25 cubic centimetres, corresponding to 0·18 per cent. of lactic acid.

TABLE I.

—	Per cent. lactic acid.		
	13° C. (55·4° F.)	18° C. (64° F.)	24° C. (75·2° F.)
Fifteen hours			
Blank	0·182	0·202	0·232
Boric acid	0·180	0·180	0·216
Formaldehyde	0·182	0·180	0·194
Twenty hours			
Blank	0·184	0·205	0·245
Boric acid	0·180	0·193	0·220
Formaldehyde	0·178	0·179	0·193
Twenty three hours.			
Blank	0·184	0·210	0·281
Boric acid	0·180	0·189	0·241
Formaldehyde	0·173	0·184	0·223
Thirty-nine hours			
Blank	0·191	0·332	0·799
Boric acid	0·178	0·259	0·618
Formaldehyde	0·173	0·209	0·500

From these results it will be noticed that at the lowest temperature—viz., 13° C.—even after 39 hours there is no increase in the acidity of the milk containing boric acid and formaldehyde, the actual titration recording a slightly lower amount of lactic acid. (The possible experimental error in these figures amount to ± 0·007 per cent. of lactic acid.) In these two milks at 18° C. there is no appreciable rise in the acidity till after 23 hours' incubation, whilst the unpreserved milk shows a gain of about 15 per cent. In considering the results at 24° C. the question arises as to what maximum acidity can be allowed to milk without its being pronounced sour.

Thorner[1] has investigated the acidity requisite to coagulate milk. Titrating under similar conditions to the above he found that milk coagulated on warming when the acidity reached 23° (cubic centimetres N/10 soda per 100 cubic centimetres of milk), corresponding to 0·207 per cent. of lactic acid. I have found the coagulating point somewhat higher than this. Normal milk was incubated at 22° C. and every few hours a fraction was removed and tested by heating to 100° C. for five minutes and also by pouring some of the milk into boiling water, the acidity being determined at the same time.

TABLE II.

No. of hours.	Degree of acidity	Per cent. of lactic acid.	Coagulation tests.
1	18·0	0·162	*Both tests negative.*
4	19·0	0·171	Ditto
6	19·2	0·173	Ditto.
8	19·6	0·176	Ditto
11	20·4	0·184	Ditto.
15	23·0	0·252	Coagulated at 100° C., but not by pouring into hot water

Therefore, when the acidity exceeds 0·25 per cent. lactic acid the milk would be considered sour and unfit for sale, and taking this as the maximum acidity allowable it will be seen from Table I. that in all cases the milk has been kept sweet by the 1 in 2000 of boric acid and 1 in 50,000 of formaldehyde for over 23 hours. In repeating this experiment with a milk incubated at 18° C. it was found that when the acidity was equal to 25·6°, or 0·230 per cent. of lactic acid, the milk was sufficiently acid to cause a slight coagulation on heating on the water-bath. It will therefore be seen that Thorner's limit of 0·207 per cent. of lactic acid is rather too low and that from 0·23 to 0·25 per cent. of lactic acid is the limit, which may be regarded as safe for dietetic purposes. Even if Thorner's limit of 0·207 per cent. of lactic acid be taken it will be seen that the quantity of boric acid and formaldehyde suggested are ample for keeping a milk sweet for 23 hours at 18° C. But the quantity of boric acid is insufficient for keeping it sweet for a longer period than 15 hours, and of formaldehyde for a longer period than 20 hours, when the temperature is as high as 24° C. The initial acidity of milk varies very considerably, and even in milk examined within an hour of the time of milking the quantity of acidity calculated as lactic acid may be as high as 0·1 per cent., so that, taking it generally, the work required of the preservative is to arrest the production of one-tenth per cent. of acidity calculated as lactic acid in the milk during the time which must necessarily elapse between the time of milking and the time of consumption.

As the souring of milk is due to the development of several organisms it by no means follows that the smell or taste of an unpalatable milk is measured by the amount of acidity as determined by titration. But as the coagulation of milk apparently depends upon this factor, irrespective of the nature of acidity, it seems reasonable to take it as a measure of the quality of milk. I have, however, observed slight coagulation in milk when the acidity has been as low as 0·194 per cent. of lactic acid.

Another important point to bear in mind is that a preservative is obviously more efficient if added to the milk at the time of milking so that the development of the organisms present in the milk is retarded from the very commencement, and this points to the conclusion that the legitimate use of preservatives should be restricted to its use by the farmer or cowkeeper and not by the middleman or vendor or consumer. It is urged by some that the consumer could preserve his milk if he thought it was necessary, but without entering into a discussion of Dr. M. K. Robinson's case, and dismissing for the moment Dr. O. Liebreich's reply to it, which in my opinion seems clearly to establish that the poisoning was not due to boric acid, such a method of dealing with the problem would open the way to future cases similar to that of Dr. Robinson in which excessive doses of preservatives might be taken by susceptible individuals.

It may not be generally known to readers of THE LANCET that in the case of butter the loss of flavour and the beginning of rancidity are very carefully gauged by experts, so that points or marks of value are assigned to butters which give their commercial value. In the report for the New Zealand Department of Agriculture for 1898 Mr. Sorensen shows that butter containing 3 per cent. of salt and ½ per cent. of boric acid and subjected to cold storage yields on keeping a butter having the greatest number of points, 37 out of 45, whilst butters with 1 per cent. of boric acid and only 2 or 3 per cent. of salt gave an inferior result, and those containing either more or less salt without boric acid had lost still more flavour. These results are extremely interesting as showing that in this particular case it is to the interest of the trader to keep the boric acid low, as from the commercial point of view the butter with ½ per cent. of boric acid has a better flavour and will fetch a better price than that containing 1 per cent.

---

[1] Chemische Zeitschrift, 1891, p 1139.

The last point which I wish to refer to is the value of feeding experiments in connexion with this subject. Those published by Mr. Foulerton and myself with milk containing formaldehyde were of value in establishing the fact that adult animals, notwithstanding the fact that their body weight was far less than that of man, could consume large quantities of milk preserved with moderate amounts of preservatives without apparent injurious effect. It has been pointed out by Dr. H. E. Annett and others that the cats used in these experiments were three months old, but we did not mention the fact that we had previously attempted to feed kittens three weeks old similar to those used by Dr. Annett. These attempts, however, were unsuccessful, as we found that kittens at this age, when taken directly from their mother, were not capable of assimilating their food when the food consisted only of undiluted and unpreserved cow's milk, and six kittens died under our hands. I attribute this partly to the fact that cow's milk is an unfit food for these young kittens, as it is well known that the characteristic of cat's milk is a very large percentage, amounting to 6 per cent., of albumin, a constituent which is only present in cow's milk to the extent of about ½ per cent., so that such food is as unsuitable for young kittens as undiluted cow's milk is for infants. It will be noticed in Dr. Annett's experiments that in these young kittens the results were very irregular, and that whereas the normal rate of increase per week should be from 30 to 40 grammes, or roughly 10 per cent. of the body weight, in kittens receiving untreated milk in some cases he actually obtained decrease in weight and in others only an increase of two or three grammes. The heavier and older the kittens the more reliable are the results. Another significant point in Dr. Annett's experiments is that the larger quantity of preservative—viz., 80 grains per gallon—did not seem so fatal as the milk containing half this amount, as it will be noticed that with the smaller quantity of preservative he obtained two deaths out of five in the third week, whereas with the larger quantity all of the animals survived this time. Similar irregular results were obtained by him with the milk containing formaldehyde, as he obtained three deaths with the weaker solution, none with the formaldehyde of 1 in 25,000, and two with the stronger solution. Before these experiments of Dr. Annett were published I had carried out a few feeding experiments with kittens about five weeks old, at which age they can take cow's milk freely, but I restricted the quantity to about 70 cubic centimetres per animal per day and used the preservative in the proportions already advocated, so that each kitten received about half a grain of boric acid per day. The results are summarised as follows:—

TABLE III.

—	Average weight in grammes of animal fed on—			
	Milk.	Milk + formaldehyde.	Milk + boric acid. (1)	(2)
First week	517	591	595	630
Second week	537	657	616	664
Third week	610	674	624	744*
Percentage increase in weight on first week.				
Second week	3·87	11·1	8·6	5·4
Third week	18·00	14·1	15·0	18·1

* In the third week this kitten was fed on formalised milk instead of on borated milk.

Making allowance for the difference between different animals and the irregularities always noticed in animal experiments, the natural increase cannot be said to be interfered with. All were active and healthy at the conclusion of the experiment. As pointed out by Dr. Liebreich we have in Dr. Annett's experiments no information given us as to the quantity of milk supplied to the kittens, and it is quite possible that they received a much larger quantity of preservative than the above. As a kitten weighs approximately one pound and I gave mine half a grain of boric acid per day, it would follow that a child six months old, weighing 12 lb., could take, therefore, six grains of boric acid a day, or, say, a pint and a half of preserved milk. If any value, therefore, is to be attached to animal experiments, the relation of body weight to the amount of preservative exhibited must be taken into account. Of course, this relation is recognised in the Pharmacopœia, but it is well known that the usual allowance for doses for children of some drugs does not obey any definite law. In the Pharmacopœia this quantity of six grains of boric acid per day for a child six months old would be about eight times the medicinal dose. I am, therefore, inclined to agree with Mr. Foulerton that experiments on animals have, after all, but a very slight bearing upon the problem under investigation. As Dr. Liebreich points out, even regarding Dr. Annett's experiments in their most favourable light they by no means prove that boric acid and formaldehyde are poisonous for young children, even in quantities largely in excess of those which would be possible in a milk diet when the preservatives were regulated in the way suggested.

MYOIDEMA IN PULMONARY TUBERCULOSIS.

By HUGH WALSHAM, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

IF in an advanced case of pulmonary tuberculosis a point on the chest wall corresponding to the clavicular origin of the pectoralis major be sharply struck with the tip of the forefinger the phenomenon usually known as "myoidema" will probably be produced. Myoidema may be divided into two varieties—viz., the fascicular and the nodular. The fascicular variety is the one most easily produced. At the point which is struck a sulcus is formed which quickly travels to the origin and insertion of the muscle, where it is lost. In the nodular variety there is formed at the point struck a small quivering tumour which, after oscillating backwards and forwards, as if uncertain of its position, for a second or two, finally comes to rest and after a few seconds gradually fades away. If the point struck be carefully watched the initial pallor produced by the blow quickly gives way to redness, reminding one forcibly of the *tache cérébrale*. This redness of the skin remains for a considerable time, occasionally for ten minutes or even longer, before it finally disappears. Both the fascicular and nodular variety may be obtained in other muscles besides the great pectoral. It is very commonly found in the deltoids and scapular muscles, especially in the infra-spinatis. After the tumour has faded away it may again be produced by another tap on the muscle, not necessarily in the same spot but near it. The phenomenon can be produced a third or even a fourth time, but not afterwards, the muscle apparently becoming fatigued and refusing to contract to the stimulus.

The phenomenon of myoidema is nothing new. The condition was described long ago by Dr. Stokes[1] of Dublin, but not under its present name. Dr. Stokes's words are as follows: "There is another highly interesting circumstance connected with percussion which we do not think has as yet been described. Some time ago on percussing a patient who had laboured under a pectoral affection with several symptoms indicative of tubercular development we were surprised to observe that after each stroke of the ends of the fingers a number of little tumours appeared answering exactly to the number and situation of the points of the fingers where they had struck the integuments of the chest. These having continued visible for a few moments subsided, but could be again made to appear on repeating the percussion." The term "myoidema" was first made use of by a surgeon, the late Mr. Lawson Tait[2], who wrote a monograph on the subject. He considered the sign to be diagnostic of pulmonary tuberculosis. Dr. Samuel West[3] in a paper on myoidema pointed out that the sign was by no means limited to cases of pulmonary tuberculosis, but that it could be obtained in a number of other wasting diseases, such as enteric fever, progressive muscular atrophy, &c. In a later paper by M. Jeanselme and M. Lermoyez[4] it is asserted that myoidema can be obtained in persons in perfect health—that it is merely a physiological phenomenon. With these authors I cannot agree. I have never been able to obtain the sign in a perfectly healthy person.

---

[1] Dublin Hospital Reports, vol. v., p. 70.
Myoidema in Phthisis, 1872.

Now as regards the value of myoidema as a sign of pulmonary tuberculosis it will be seen from the above quotations that authors are by no means agreed on the point. Dr. Stokes says: "There is nothing in this muscular irritability peculiar to phthisis, but that it is commonly connected with irritation of the lung or pleura there can be no doubt, and in this way, like other signs of irritation, it becomes available in the diagnosis of phthisis." Sir William Broadbent is reported to have said in the discussion on the preventative and remedial treatment of tuberculosis at the meeting of the British Medical Association at Portsmouth that among the physical signs of early phthisis he regarded two as of great value, viz., an occasional sibilant râle at the apex and myoidema, the latter practically being never absent in early phthisis Dr. Stokes also says that myoidema is always most evident in the earlier periods. On my appointment as an assistant physician to the City of London Hospital for Diseases of the Chest, now some four years ago, I determined to investigate the value of this sign in pulmonary tubercle. Dr. West says in his paper that he had no statistics to show its relative frequency in phthisis I have examined every case of pulmonary tuberculosis in my out-patient room with reference to the presence or absence of this sign. The total number of cases available is 1000. Firstly, I cannot agree with those physicians who maintain that myoidema is an early sign. I have never found it in an early case. It certainly only becomes well marked when the wasting has advanced beyond a certain degree. A suspicion of the fascicular variety may sometimes exist in an early case, but never the nodular. In fact, the rule that the more the wasting the more marked is the myoidema has few exceptions. The blush following the tap on the muscle is almost as characteristic as the myoidema itself. Authors differ, again, as to the question of position Some maintain that myoidema is only found on the affected side in cases of unilateral phthisis, if such a condition exists. Others, again, say that it is to be found only over softening tuberculous foci. I am sure, however, that it may always be obtained on both sides when it is carefully looked for. I do not think that the stage of the disease in which the lung may be makes any difference to its production I have often in very advanced cases with great emaciation been unable to obtain the phenomenon, the great pectoral muscle apparently being too much wasted to produce it Dr. West states that the electrical reactions have been found altered in these cases. I have made many observations with both battery and coil currents but could find no alteration in the normal electrical reactions.

I think that cases of pulmonary tuberculosis may be divided into three classes with respect to this sign, corresponding closely to the three classical stages of the disease In the first class I should say that the sign was absent in the vast majority of cases, although a faint fibrillar contraction may occasionally be obtained. In the second class the fibrillar variety can always be obtained and frequently the nodular variety, and in the third class the nodular variety may nearly always be produced, with the exception stated above. I think that myoidema is nearly valueless as an early sign of pulmonary tuberculosis. It only becomes well marked when other physical signs leave no doubt about the diagnosis of pulmonary tubercle. The sign is of value, I think, as indicating the condition of the muscular system of the patient and as showing approximately the amount of wasting that has taken place.

BRISTOL MEDICAL CHARITIES.—During 1899 the employés of Messrs. J. S. Fry contributed £746 to the medical charities of Bristol.

DEPILATION BY ROENTGEN RAYS.

BY NEVILLE WOOD, M.D. DURH., M.R.C.P. LOND.

I VENTURE to hope that the following case may prove of interest as indicating the value of the treatment by the Roentgen rays and as a contribution to the study of dosage according to the result which is aimed at.

A woman, aged 22 years, consulted me in November, 1898, on account of a considerable overgrowth of hair on the face. The history given was that 14 months previously one inferior turbinate bone had been removed and that about three months subsequently the hair on her face, which was not previously excessive, took on active growth. During the two or three months before her visit it had become sufficiently conspicuous to excite frequent comment by acquaintances and strangers. At the date of her visit the following note was made: "A healthy-looking, fresh-complexioned brunette; all the bodily functions stated to be regularly performed, nothing remarkable about the hairy scalp, and the body hair said not to be in excess. Face.—On the upper lip from a point half an inch from the middle line and extending outwards on each side for three-quarters of an inch there is a moderately close growth of dark, rather thick hairs, mostly about a quarter of an inch long. In front of the ears there is a slight excess of hair, and this growth is continued on each side down to the angle of the jaws, the length of the hairs increasing as this point is reached. On the chin the hairy growth is most conspicuous and disfiguring. From the point, extending one inch upwards, three-quarters of an inch backwards, and one inch transversely, there is a groundwork of closely set down and in addition numerous thick dark hairs from one-eighth of an inch to one inch in length."

For this reason and on account of the known incidence of dermatitis it was decided to treat first this area and it was found convenient to begin with the front part of the chin, the rest of the face and neck being protected with a lead-foil mask. The sittings took place, when possible, six times a week and the duration of each sitting was 10 minutes. The distance between the anticathode and the skin was between six and seven inches. The current through the primary coil was maintained at about five ampères and the number of interruptions varied between 250 and 300 per second. After 14 exposures it was noticed that the darker hairs had lost some of their lustre and a week later there was an obvious lessening in their number. The shed hairs were brittle and pale in colour with atrophic bulbs, while microscopically the normal striation was indistinct and the medullary substance appeared to be collected into separate nodes with clear intervening spaces During this period occasional slight reddening of the skin was noticed. The treatment continued till 45 exposures had been given to the point of the chin, when the whole of the very thick downy and hairy growth had disappeared except nine hairs which remained at least a week after the total removal of the others. Mechanical interference having previously, for obvious reasons, been avoided it was now judged right to ascertain the condition of these residual hairs. On applying the gentlest traction to one it was found that it was really separated at its bulb, which was deeply placed but was held by a *more* superficial part of the root-sheath so that the rest were left untouched, and as it was now clear that the object aimed at had been attained, and as the skin was somewhat reddened a message was sent that treatment should be directed only to the under surface of the chin. This message miscarried, so that the front received a few more exposures, and a sharp attack of dermatitis ensued, which, however, speedily subsided under simple treatment. 20 exposures were also given to the under part of the chin and 10 consecutively to the cheeks. The result, *some* eight months after the cessation of treatment, can probably be safely judged, since for more than three months there has been no change in the condition. The front of the chin, which received more than 40 exposures, remains quite free from down and hair. The under surface, which had 20 exposures, is cleared of down, but within three months of suspension of treatment a few thick hairs returned. Their number, however, has not since increased, and they are so sparse that electrolysis would seem to be indicated for them. The cheeks, which had a small number of exposures, I am informed, temporarily lost all their hair, but it has now interesting as showing that in this particular case it is to the interest of the trader to keep the boric acid low, as from the commercial point of view the butter with ½ per cent. of boric acid has a better flavour and will fetch a better price than that containing 1 per cent.

The last point which I wish to refer to is the value of feeding experiments in connexion with this subject. Those published by Mr. Foulerton and myself with milk containing formaldehyde were of value in establishing the fact that adult animals, notwithstanding the fact that their body weight was far less than that of man, could consume large quantities of milk preserved with moderate amounts of preservatives without apparent injurious effect. It has been pointed out by Dr. H. E. Annett and others that the cats used in these experiments were three months old, but we did not mention the fact that we had previously attempted to feed kittens three weeks old similar to those used by Dr. Annett. These attempts, however, were unsuccessful, as we found that kittens at this age, when taken directly from their mother, were not capable of assimilating their food when the food consisted only of undiluted and unpreserved cow's milk, and six kittens died under our hands. I attribute this partly to the fact that cow's milk is an unfit food for these young kittens, as it is well known that the characteristic of cat's milk is a very large percentage, amounting to 6 per cent., of albumin, a constituent which is only present in cow's milk to the extent of about ½ per cent., so that such food is as unsuitable for young kittens as undiluted cow's milk is for infants. It will be noticed in Dr. Annett's experiments that in these young kittens the results were very irregular, and that whereas the normal rate of increase per week should be from 30 to 40 grammes, or roughly 10 per cent. of the body weight, in kittens receiving untreated milk in some cases he actually obtained decrease in weight and in others only an increase of two or three grammes. The heavier and older the kittens the more reliable are the results. Another significant point in Dr. Annett's experiments is that the larger quantity of preservative—viz., 80 grains per gallon—did not seem so fatal as the milk containing half this amount, as it will be noticed that with the smaller quantity of preservative he obtained two deaths out of five in the third week, whereas with the larger quantity all of the animals survived this time. Similar irregular results were obtained by him with the milk containing formaldehyde, as he obtained three deaths with the weaker solution, none with the formaldehyde of 1 in 25,000, and two with the stronger solution. Before these experiments of Dr. Annett were published I had carried out a few feeding experiments with kittens about five weeks old, at which age they can take cow's milk freely, but I restricted the quantity to about 70 cubic centimetres per animal per day and used the preservative in the proportions already advocated, so that each kitten received about half a grain of boric acid per day. The results are summarised as follows:—

TABLE III.

—	Average weight in grammes of animal fed on—			
	Milk.	Milk + formaldehyde.	Milk + boric acid. (1)	(2)
First week	517	591	595	630
Second week ...	537	657	646	664
Third week	610	674	684	744*
	Percentage increase in weight on first week.			
Second week ..	3·87	11·1	8·6	5·4
Third week	18·00	14·1	15·0	18·1

* In the third week this kitten was fed on formalised milk instead of on borated milk.

Making allowance for the difference between different animals and the irregularities always noticed in animal experiments, the natural increase cannot be said to be interfered with. All were active and healthy at the conclusion of the experiment. As pointed out by Dr. Liebreich we have in Dr. Annett's experiments no information given us as to the quantity of milk supplied to the kittens, and it is quite possible that they received a much larger quantity of preservative than the above. As a kitten weighs approximately one pound and I gave mine half a grain of boric acid per day, it would follow that a child six months old, weighing 12 lb., could take, therefore, six grains of boric acid a day, or, say, a pint and a half of preserved milk. If any value, therefore, is to be attached to animal experiments, the relation of body weight to the amount of preservative exhibited must be taken into account. Of course, this relation is recognised in the Pharmacopœia, but it is well known that the usual allowance for doses for children of some drugs does not obey any definite law. In the Pharmacopœia this quantity of six grains of boric acid per day for a child six months old would be about eight times the medicinal dose. I am, therefore, inclined to agree with Mr. Foulerton that experiments on animals have, after all, but a very slight bearing upon the problem under investigation. As Dr. Liebreich points out, even regarding Dr. Annett's experiments in their most favourable light they by no means prove that boric acid and formaldehyde are poisonous for young children, even in quantities largely in excess of those which would be possible in a milk diet when the preservatives were regulated in the way suggested.

MYOIDEMA IN PULMONARY TUBERCULOSIS.

BY HUGH WALSHAM, M.A., M.D. CANTAB.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

IF in an advanced case of pulmonary tuberculosis a point on the chest wall corresponding to the clavicular origin of the pectoralis major be sharply struck with the tip of the forefinger the phenomenon usually known as "myoidema" will probably be produced. Myoidema may be divided into two varieties—viz., the fascicular and the nodular. The fascicular variety is the one most easily produced. At the point which is struck a sulcus is formed which quickly travels to the origin and insertion of the muscle, where it is lost. In the nodular variety there is formed at the point struck a small quivering tumour which, after oscillating backwards and forwards, as if uncertain of its position, for a second or two, finally comes to rest and after a few seconds gradually fades away. If the point struck be carefully watched the initial pallor produced by the blow quickly gives way to redness, reminding one forcibly of the *tache cérébrale*. This redness of the skin remains for a considerable time, occasionally for ten minutes or even longer, before it finally disappears. Both the fascicular and nodular variety may be obtained in other muscles besides the great pectoral. It is very commonly found in the deltoids and scapular muscles, especially in the infra-spinatis. After the tumour has faded away it may again be produced by another tap on the muscle, not necessarily in the same spot but near it. The phenomenon can be produced a third or even a fourth time, but not afterwards, the muscle apparently becoming fatigued and refusing to contract to the stimulus.

The phenomenon of myoidema is nothing new. The condition was described long ago by Dr. Stokes[1] of Dublin, but not under its present name. Dr. Stokes's words are as follows: "There is another highly interesting circumstance connected with percussion which we do not think has as yet been described. Some time ago on percussing a patient who had laboured under a pectoral affection with several symptoms indicative of tubercular development we were surprised to observe that after each stroke of the ends of the fingers a number of little tumours appeared answering exactly to the number and situation of the points of the fingers where they had struck the integuments of the chest. These having continued visible for a few moments subsided, but could be again made to appear on repeating the percussion." The term "myoidema" was first made use of by a surgeon, the late Mr. Lawson Tait[2], who wrote a monograph on the subject. He considered the sign to be diagnostic of pulmonary tuberculosis. Dr. Samuel West[3] in a paper on myoidema pointed out that the sign was by no means limited to cases of pulmonary tuberculosis, but that it could be obtained in a number of other wasting diseases, such as enteric fever, progressive muscular atrophy, &c. In a later paper by M. Jeanselme and M. Lermoyez[4] it is asserted that myoidema can be obtained in persons in perfect health—that it is merely a physiological phenomenon. With these authors I cannot agree. I have never been able to obtain the sign in a perfectly healthy person.

[1] Dublin Hospital Reports, vol. v., p 70.
[2] Myoidema in Phthisis, 1872.

Now as regards the value of myoidema as a sign of pulmonary tuberculosis it will be seen from the above quotations that authors are by no means agreed on the point. Dr. Stokes says: "There is nothing in this muscular irritability peculiar to phthisis, but that it is commonly connected with irritation of the lung or pleura there can be no doubt, and in this way, like other signs of irritation, it becomes available in the diagnosis of phthisis." Sir William Broadbent is reported to have said in the discussion on the preventative and remedial treatment of tuberculosis at the meeting of the British Medical Association at Portsmouth that among the physical signs of early phthisis he regarded two as of great value, viz., an occasional sibilant râle at the apex and myoidema, the latter practically being never absent in early phthisis. Dr. Stokes also says that myoidema is always most evident in the earlier periods. On my appointment as an assistant physician to the City of London Hospital for Diseases of the Chest, now some four years ago, I determined to investigate the value of this sign in pulmonary tubercle. Dr. West says in his paper that he had no statistics to show its relative frequency in phthisis. I have examined every case of pulmonary tuberculosis in my out-patient room with reference to the presence or absence of this sign. The total number of cases available is 1000. Firstly, I cannot agree with those physicians who maintain that myoidema is an early sign. I have never found it in an early case. It certainly only becomes well marked when the wasting has advanced beyond a certain degree. A suspicion of the fascicular variety may sometimes exist in an early case, but never the nodular. In fact, the rule that the more the wasting the more marked is the myoidema has few exceptions. The blush following the tap on the muscle is almost as characteristic as the myoidema itself. Authors differ, again, as to the question of position Some maintain that myoidema is only found on the affected side in cases of unilateral phthisis, if such a condition exists. Others, again, say that it is to be found only over softening tuberculous foci. I am sure, however, that it may always be obtained on both sides when it is carefully looked for. I do not think that the stage of the disease in which the lung may be makes any difference to its production I have often in very advanced cases with great emaciation been unable to obtain the phenomenon, the great pectoral muscle apparently being too much wasted to produce it Dr. West states that the electrical reactions have been found altered in these cases. I have made many observations with both battery and coil currents but could find no alteration in the normal electrical reactions.

I think that cases of pulmonary tuberculosis may be divided into three classes with respect to this sign, corresponding closely to the three classical stages of the disease In the first class I should say that the sign was absent in the vast majority of cases, although a faint fibrillar contraction may occasionally be obtained. In the second class the fibrillar variety can always be obtained and frequently the nodular variety, and in the third class the nodular variety may nearly always be produced, with the exception stated above. I think that myoidema is nearly valueless as an early sign of pulmonary tuberculosis. It only becomes well marked when other physical signs leave no doubt about the diagnosis of pulmonary tubercle. The sign is of value, I think, as indicating the condition of the muscular system of the patient and as showing approximately the amount of wasting that has taken place.

DEPILATION BY ROENTGEN RAYS.

BY NEVILLE WOOD, M.D. DURH., M.R.C.P. LOND.

I VENTURE to hope that the following case may prove of interest as indicating the value of the treatment by the Roentgen rays and as a contribution to the study of dosage according to the result which is aimed at.

A woman, aged 22 years, consulted me in November, 1898, on account of a considerable overgrowth of hair on the face. The history given was that 14 months previously one inferior turbinate bone had been removed and that about three months subsequently the hair on her face, which was not previously excessive, took on active growth. During the two or three months before her visit it had become sufficiently conspicuous to excite frequent comment by acquaintances and strangers. At the date of her visit the following note was made: "A healthy-looking, fresh complexioned brunette; all the bodily functions stated to be regularly performed, nothing remarkable about the hairy scalp, and the body hair said not to be in excess. Face —On the upper lip from a point half an inch from the middle line and extending outwards on each side for three quarters of an inch there is a moderately close growth of dark, rather thick hairs, mostly about a quarter of an inch long. In front of the ears there is a slight excess of hair, and this growth is continued on each side down to the angle of the jaws, the length of the hairs increasing as this point is reached. On the chin the hairy growth is most conspicuous and disfiguring. From the point, extending one inch upwards, three-quarters of an inch backwards, and one inch transversely, there is a groundwork of closely set down and in addition numerous thick dark hairs from one-eighth of an inch to one inch in length."

For this reason and on account of the known incidence of dermatitis it was decided to treat first this area and it was found convenient to begin with the front part of the chin, the rest of the face and neck being protected with a lead foil mask. The sittings took place, when possible, six times a week and the duration of each sitting was 10 minutes. The distance between the anticathode and the skin was between six and seven inches. The current through the primary coil was maintained at about five ampères and the number of interruptions varied between 250 and 300 per second. After 14 exposures it was noticed that the darker hairs had lost some of their lustre and a week later there was an obvious lessening in their number. The shed hairs were brittle and pale in colour with atrophic bulbs, while microscopically the normal striation was indistinct and the medullary substance appeared to be collected into separate nodes with clear intervening spaces During this period occasional slight reddening of the skin was noticed. The treatment continued till 45 exposures had been given to the point of the chin, when the whole of the very thick downy and hairy growth had disappeared except nine hairs which remained at least a week after the total removal of the others. Mechanical interference having previously, for obvious reasons, been avoided it was now judged right to ascertain the condition of these residual hairs On applying the gentlest traction to one it was found that it was really separated at its bulb, which was deeply placed but was held by a more superficial part of the root-sheath so that the rest were left untouched, and as it was now clear that the object aimed at had been attained, and as the skin was somewhat reddened a message was sent that treatment should be directed only to the under surface of the chin. This message miscarried, so that the front received a few more exposures, and a sharp attack of dermatitis ensued, which, however, speedily subsided under simple treatment. 20 exposures were also given to the under part of the chin and 10 consecutively to the cheeks. The result, some eight months after the cessation of treatment, can probably be safely judged, since for more than three months there has been no change in the condition. The front of the chin, which received more than 40 exposures, remains quite free from down and hair. The under surface, which had 20 exposures, is cleared of down, but within three months of suspension of treatment a few thick hairs returned. Their number, however, has not since increased, and they are so sparse that electrolysis would seem to be indicated for them. The cheeks, which had a small number of exposures, I am informed, temporarily lost all their hair, but it has now re-grown as before, and this part will not be dealt with again till the patient can arrange for continuous sittings.

It would seem, if the above case can be taken as a guide, that 10 short exposures are useless, that about 20 exposures will clear the ground for electrolysis or simple traction if for any reason the ray treatment has to be suspended, while some number of exposures between 30 and 40 will probably result in permanent alopecia, though it is to be expected that with further experience this number may be reduced, so that a treatment which neither pains nor disfigures may take its proper position in practical therapeutics. It is right to state that the whole of the technical arrangements were designed and most intelligently carried out by Mr. Isenthal, to whom I wish to express my great indebtedness.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF RECTAL DEFORMITY.

By I. G. Modlin, M.D., B.S. Durh.,

HONORARY SURGEON TO MONKWEARMOUTH HOSPITAL.

During September, 1899, I was asked to operate on a woman for deformity in the perineal region. On examination I found a well-formed perineum and a slight dimple in the position in which the anus should be, but no opening or sphincter. The vulva to external appearances seemed to be normal, but on separating the labia a moveable septum was seen, which proved to be formed of the posterior vaginal and anterior rectal walls. It was about one-sixteenth of an inch in thickness and was freely moveable from before backwards. The condition was not one of cloaca. The vagina and rectum were, excepting at their orifices, intact, so that the urethra, vagina, and rectum all opened into one common vulva. The vaginal and rectal tubes might be compared to the two barrels of a double-barrelled gun, the muzzles of which were seen on separating the labia. The patient was 24 years of age, had been married four years, and had had two abortions. The condition described had evidently existed from birth. It had given rise to no symptoms beyond an obstinate constipation and the unpleasantness due to the abnormality. The constipation was extremely troublesome and had probably been to some extent caused by the patient putting off the act of defecation as long as possible owing to the pain and discomfort produced. An aperient and generally an enema were necessary to procure relief. The act usually took about half an hour and caused such severe pain that the patient nearly always fainted, and it always caused hæmorrhage.

After the usual preparation I operated, the patient being anæsthetised with chloroform. I first cut through the perineum in the middle line *from* the posterior angle of the vulva to the normal situation of the anus. I continued the incision upwards through the fibrous tissue filling in the space between the rectum and the coccyx. I then separated the posterior wall of the rectum for *about two inches*. The next step was to dissect up the recto-vaginal septum, thus separating the two passages. The sides of the rectum were then separated from the surrounding tissue and the lower end of the rectum was freely moveable. I brought it backwards through the opening I had made for it in the fibrous tissue to its normal situation and sutured it with fine silk sutures posteriorly and laterally to the skin of my first perineal incision. I then again brought to the middle line the two flaps produced by the first incision to form the new perineum and sutured them together with silk sutures, deep and superficial. The *posterior border* of this new perineum was sutured to the anterior wall of the rectum, this completing the new anus; and the anterior border of the new perineum was sutured to the raw surface of the posterior vaginal wall, thus completing the vagina.

The case went on very promisingly, the temperature never rising above 99·8° F. for 12 days after the operation, when constipation proved very troublesome; there had been a motion every day, but scybalous masses formed, so that chloroform was again administered and the scybala were broken down with a Volkmann's spoon. From this time the patient made an uninterrupted recovery. The present condition is most satisfactory. There is a good, firm perineum one and a half inches long and the vagina is perfectly normal. The constipation is greatly improved and is still improving under treatment by cascara, strychnine, belladonna, and aloes. There is no hæmorrhage with defecation and the act is easily performed. There is perfect control over the bowel, so that I believe the muscular fibres of the rectum have accommodated themselves to circumstances and have undertaken the functions of a sphincter.

I publish this case as I have never seen reported, or heard of, one in which the condition of the parts was precisely similar.

Sunderland.

SOME REMARKS ON THE DIAPHRAGM.

By Robert Lee, M.D. Cantab., F.R.C.P. Lond.

One of the symptoms that occur frequently in influenza is pain in the back and round the lower part of the thorax. Having made observations from personal experience I have come to the conclusion that this symptom is due to some trouble affecting the diaphragm and that probably some of the symptoms which we find difficult to explain may be referred to the peculiar characters of the diaphragm and the important part which it plays in the physics of respiration. The line of pain round the thorax is that of the insertion of the diaphragm tendon, while that in the back is due probably to its connexion with the two lowest ribs and the transverse processes of the two first lumbar vertebræ. The question of interest when we are considering *the diaphragm* is how far the sympathetic nervous system regulates its action. The two ganglia diaphragmatica lying just above the suprarenal capsules connect the phrenic nerve with the solar plexus, and as the diaphragm is in action at all times and to a great extent independently of the will we may conclude that it differs from the muscles which are supplied only with voluntary nerves.

Another peculiar symptom of influenza is the dry and somewhat spasmodic cough, which is apparently due to a spasm of the diaphragm, and it has occurred to me that the *cases of collapse or sudden death* which we have been accustomed to attribute to heart-disease, though we find nothing clearly to account for them, may be due to some cramp or spasm of the diaphragm.

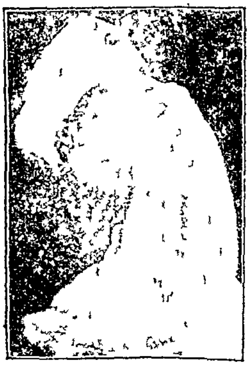
When we consider how vomiting, hiccough, and certain other disturbances of the thoracic and abdominal organs are apparently caused by the action of the diaphragm we may give more attention to this very important muscle than it has yet received. Some years ago, when the subject of sudden death required my attention and I had opportunities of making many post-mortem examinations for Mr. Bedford and others of Her Majesty's coroners, it was not by any means unusual to find no definite cause to account for death. Whether the diaphragm is liable to cramp and consequently respiration may be arrested suggests itself as a question worth reflecting upon, and though it is not in any way proper to theorise on such a matter we may do well to make inquiry by observation or otherwise when reason induces us.

West Kensington, W.

POTT'S DISEASE OR FRACTURE OF VERTEBRÆ?

By W. R. Townsend, M.D.

The *patient, a girl, six years* of age, had an obscure history. Two years ago, when living with her grandmother, after an accident in which she fell down a flight of stairs, striking the back of her neck, a bony prominence was noticed. This was accompanied by difficult respiration and a habit of supporting her head with the hand placed under the chin. Kyphosis was marked, as shown by the accompanying illustration, the sixth and seventh cervical and the first and second dorsal vertebræ being involved. There was a depression of the upper cervical vertebræ. Dr. A. B. Judson, when the case was shown at the Section of Orthopædic Surgery at the New York Academy of Medicine, thought that the number of the involved vertebræ pointed away from fracture and towards Pott's disease Dr Sayre said that although a forward position of the head in cervical Pott's disease was frequently attended by difficult breathing, he thought that the child had suffered a fracture and recalled the case of a man who had fallen downstairs striking the back of his head, when partial paralysis of the arm developed from pressure



Pott's disease or vertebral fracture?

The treatment was not doubtful even if the diagnosis was not clear The affected vertebræ should be given complete rest This must be effected either by a plaster jacket and head spring or by a posterior spinal support and chin piece The latter would be less conspicuous and give better support, with or without the addition of supports going up the back of the head, as might be determined by the progress of treatment, which should be prolonged until the disappearance of all signs of an acute condition Ultimately the patient should carry the head erect without much deformity, as is the rule in cervical disease thus treated

ROYAL FREE HOSPITAL

A CASE OF COMPOUND SEPARATION OF THE LOWER EPIPHYSIS OF THE FEMUR RECOVERY WITH USEFUL LIMB

(Under the care of Mr E W ROUGHTON)

THE valuable suggestion made by Mr Jonathan Hutchinson, jun as to the treatment of separation of the lower epiphysis of the femur is not equally applicable to all cases The complete replacement of the separated epiphysis effected by flexion is in part dependent on the integrity of the periosteum, if this is extensively separated or if it sloughs then the *forced flexion of the knee* will not suffice to bring into apposition the displaced surfaces and this is probably the explanation of the difficulty met with in the case recorded below Compound separations also are less suited for this method of treatment which is however, highly ingenious and of the greatest service in suitable cases For the notes of the case we are indebted to Mr C Sprawson, late house surgeon

A boy aged five and three-quarter years was taken to the Royal Free Hospital in a collapsed state on July 23th, 1899 *He had been riding on the back of a cab* and had caught first his right and then his left leg between the spokes of one of the wheels *On examination* there was on the left side a simple fracture in the upper third of the femur, on the right side the diaphysis of the femur was protruding to a distance of three inches through a popliteal wound about five inches in vertical length The periosteum was stripped from this part whilst the lower end presented the roughly stellated facet which is characteristic of an epiphyseal junction The patient in addition was slightly concussed The wound was purified as far as possible and the boy was admitted into the ward Two hours later chloroform was administered in order that a more thorough examination might be made The popliteal artery was now found to be uninjured and the arteria dorsalis pedis could be felt pulsating With a finger in the wound the lower epiphysis could be felt to be rotated backwards as is usual whilst the displacement could be reduced in the manner recently described by Mr J Hutchinson, jun —i e, by right angled traction on the leg with complete flexion of the knee After purification of the wound and its surroundings two tubes were inserted for drainage into the wound a dressing was applied, and the leg was bandaged in a completely flexed position hot water bottles and sand bags being used to assist in propping it up The fracture of the left femur was treated by being placed on a Mackintyre splint On the next day (July 29th) the leg was found to have slipped from its completely flexed position to an angle of about 45 degrees with the thigh The temperature was 102° F and the child was slightly delirious At this time the urine was found readily to reduce Fehling's solution, possibly an after effect of the anæsthetic On the 30th the temperature being 103 6° and the patient very delirious Mr *Roughton ordered the head to be shaved* and an ice bag to be applied On the 31st it was evident that the wound was very septic and numerous periosteal sloughs could be seen The child was still delirious and the leg was kept at an angle of about from 45 to 60 degrees The flexed condition of the limb was painful if beyond 60 degrees and was difficult to maintain even at this, the displacement of the epiphysis recurred, however acute the angle The dorsalis pedis artery could still be easily felt pulsating

On August 1st an anæsthetic was given The sloughs were removed as far as possible and the wound was syringed out with a 1 in 40 carbolic lotion, one drainage tube was left in and the limb was fixed upon a posterior right angled *splint, intended originally for an anterior arm splint* The left leg was now put up upon a long Liston splint and extension was applied in *order to* keep the boy more steady in the bed On the 3rd the delirium ceased although the evening temperature was still 102° For the next few days the limb did not improve, the smell from the wound was very foul the position of the epiphysis was not good and the daily dressings caused the child great pain His general condition was feeble although he took his food very well It was evident that drainage was imperfect On the 11th, therefore Mr Roughton examined the limb under an anæsthetic with a view to determine the question of amputation Deciding to give the limb a further chance Mr Roughton sawed off the lower half inch of the shaft of the femur which was necrosed, and chipped off other fragments up to the line of demarcation between the dead and living bone Much periosteal slough was removed and it was now *found* that the knee joint was *affected and* full of pus The whole wound was syringed out, the posterior wound was enlarged *and two anterior* vertical incisions were made one on either side of the patella, drainage tubes being passed through from these to the posterior wound The limb was now put up in a straight position and on the next day, for the sake of convenience in dressing the wound a long Liston splint with a bracketed interruption at the knee joint was applied and an extension of six pound weight was put on below the knee

For the next week the boy seemed to be rather better, although there was still much purulent and foul discharge On August 23rd, however his temperature at last came down to normal beyond which it did not rise at any later date On Sept 11th he was much better and smaller drainage tubes were used These were omitted altogether a week later, when also the extension was removed from both legs and the splint was removed *from the left* side The left femur was found to have united There was half an inch shortening of [illegible] slight flexion making an angle of [illegible] knee joint. A very small the articulation. On Oct. 10th the limb was put up in plaster-of-Paris casing, the knee being still slightly flexed and the foot being put up at a right angle as it had acquired a position of partial decubitus. On the 28th the plaster-of Paris was removed and a Mackintyre splint was used with the idea of affecting a complete straightening. This was so far successful that at the present time the flexion is very slight. The wounds are now all healed and the patient's general condition is very good.

Remarks by Mr. SPRAWSON.—Recovery from an accident of the above nature with a useful limb is uncommon. Out of 13 cases of compound separation recorded in detail in Poland's book on "Traumatic Separation of Epiphyses" two were fatal, six suffered amputation, whilst the remaining five recovered with their limbs. In all but one of these five a piece of the diaphysis was sawn away, either at the time to effect reduction or subsequently, as in the above case. In the one exception there was one inch of shortening at the time of recovery, so that there must be some doubt here as to the position of the parts, since in the case above recorded there is but half an inch shortening and this is the exact length of bone removed at the operation. In Mr. J. Hutchinson, jun.'s, recent paper 30 cases are referred to with six cases of recovery with useful limb. The most important factor in the result is the condition of the popliteal artery; in a case admitted to the Royal Free Hospital under the care of Mr. J. Berry, otherwise similar to the above, the artery being torn across, primary amputation was performed. As is seen, the method recommended in the paper of Mr. J. Hutchinson, jun., and Mr. H. L. Barnard in THE LANCET of May 13th, 1899, p. 1275, was adopted in the case now published. Having regard to this the following criticism may be offered. Anything like complete flexion was very painful; it was difficult to maintain owing to the slipping of the bandage; it did not prevent the recurrence of the displacement; and, above all, it put the wound under bad conditions as regards drainage. Hitherto there has been no account given of the subsequent history of the limb in these cases. Most of the accidents occur in boys of from five to ten years of age. It would be of great interest to know the comparative length of the leg ten years later.

EDEN HOSPITAL, CALCUTTA.

A CASE OF ECTOPIC GESTATION; ABDOMINAL SECTION AND REMOVAL OF UNRUPTURED TUBE; RECOVERY.

(Under the care of Captain H. M. EARLE, I.M.S , late resident surgeon.)

THE prognosis in cases of tubal gestation is chiefly dependent on an early recognition of the condition, for when the pregnancy is diagnosed before rupture has occurred the operation for removal of the tube with its contents is comparatively easy and safe. A case in many ways similar to that described below was reported in THE LANCET of July 2nd, 1898, p. 26. Hofmeier[1] gives the results of 14 cases of extra-uterine pregnancy; in nine of these an operation was performed and only one patient died; of the five remaining cases in which no operation was done one patient died from hæmorrhage and one from septicæmia, and three patients recovered; in two of the cases there was spontaneous atrophy of the swelling and in one a lithopædion formed. Mr. J. W. Taylor in his Ingleby Lectures, delivered at Mason College, Birmingham, in 1898[2] mentioned that in his own series of 37 cases in which an operation was performed there was only one death, and in Mr. Mayo Robson's 23 cases there was also only one death. Probably the mortality in all cases of extra-uterine gestation in which an operation is performed, is less than 5 per cent.

A married woman, aged 34 years, was admitted into the Eden Hospital, Calcutta, on Oct. 7th, 1899, with a previous history of having had five children and one abortion. The last child was born two years previously. The patient stated that she had been regular up to August last when she missed a period. About Sept. 9th, when her period was due, she felt very ill suddenly and this was followed by great pain shooting up from the left side over the abdomen. Two or three days later she passed a big clot. She had a second attack of faintness and pain a few days after this. Prior to the first attack she noticed that the breasts were somewhat fuller than usual. Ever since the first attack she had suffered from slight irregular discharges of blood from the vagina and paroxysmal pain in the left side. Morning sickness and ptyalism had been present both before and since the first attack. On examination the uterus was found to be retroverted and somewhat enlarged, with a soft cervix and patulous os. Lying high up and to the left of the uterus and pushing it somewhat over to the right was felt an elastic mass which was very tender on pressure.

Ectopic gestation having been diagnosed operative interference was decided on. The abdomen was opened by a three-inch incision in the median line below the umbilicus. The incision was afterwards extended upwards another inch. The left Fallopian tube, dilated to about the size of a goose's egg, was found to be lying in a bed of intestinal and omental adhesions. At first it looked as if removal of the tube would be impossible without causing some serious damage; separation of the adhesions was, however, effected. The pedicle was then clamped and ligatured as quickly as possible and the tube was removed. The pedicle was then dropped back into the pelvic cavity. During separation of the adhesions a small rupture of the tube with smart hæmorrhage occurred (no previous leaking had taken place). A finger was placed over this to prevent blood escaping into the abdominal cavity until the clamping of the pedicle could be effected, when the bleeding ceased. The cavity left by the removal of the tube was now sponged dry and the abdominal wound was sewn up with silkworm-gut sutures. No drainage was employed. The sutures were removed on the eighth day. The recovery was uneventful with the exception that the subcutaneous tissue did not unite by first intention. This was no doubt due to the extreme nervous restlessness of the patient.

Remarks by Captain EARLE.—On examination of the tube, the fœtus, which appeared to be of from six to eight weeks' development, was found embedded in recent blood-clot and lying inside a membranous sac of the size of a small hen's egg. The sac was surrounded by recent blood-clot about a quarter of an inch in thickness. The wall of the tube was somewhat thickened for the most part, but was becoming very thin at certain points where, no doubt, rupture would very soon have occurred in the ordinary course of events. I am indebted to Captain Bird, I.M.S., for his valuable assistance during the operation.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Mastoid Operation for the Cure of Chronic Purulent Otorrhœa: Methods and Indications.

A MEETING of this society was held on Jan. 23rd, Mr. THOMAS BRYANT, the President, being in the chair.

Mr. CHARLES A. BALLANCE made a communication on the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa, with special reference to the immediate healing of the cavity in the bone by means of epithelial grafts. It was pointed out in the first place that the progress in the surgical treatment of suppurations in the temporal bone during the last 20 years was due both to an increase in anatomical and pathological knowledge and to the adoption of true surgical principles, such as were applicable in all operations on bone. The peculiarity of these operations depended on the importance of the structures around. The selection of cases for the complete mastoid operation was surrounded with difficulty, and large experience rather than rigid rule was the best safeguard against, on the one hand, the risk of delay and, on the other, the performance of an unnecessary operation. The cure of chronic otorrhœa could not be effected by a simple opening into the antrum. The complete mastoid operation which involved surgical damage to the tympanic structures was inapplicable to and unjustifiable in acute cases. Mr. Ballance proposed that typical intractable cases of chronic otorrhœa should be treated by two operations: first, the operation for the removal of the disease—namely, the complete mastoid operation, and, secondly, the operation for the healing of the wound—namely by the epithelial grafting of the raw bone cavity The operations were very fully described and notes of 20 cases were appended Six patients were exhibited showing the successful results of the operation The systematic employment of epithelial grafts was advocated

---

[1] Centralblatt für Gynäkologie, No. 51, 1895.
[2] THE LANCET, June 25th, 1898, p. 1739.

Sir WILLIAM DALBY contributed a paper on Cases of Chronic Purulent Otorrhœa suitable for the Mastoid Operation His remarks dealt chiefly with the selection of cases of long standing for the complete operation with skin grafting Those in which the operation was undoubtedly necessary were first cases in which septicæmia had commenced, secondly cases in which there was dead or carious bone in the tympanic cavity accompanied by ominous symptoms often repeated, and thirdly whenever there was evidence of mastoid disease of long or short standing On the other hand, the question of operation was an open one in a certain proportion of cases where although there was evidence of dead or diseased bone there was no reliable history of ominous symptoms Similarly in patients with intractable otorrhœa without bone disease or ominous symptoms each case must be treated on its own merits Cases were also described in which a less complete operation (which however, included free posterior drainage) was necessary In discussing this question of operation it should be remembered that a large number of people went through long lives with perforations which at times discharged slightly, and at other times arrived by careful treatment at a dry or apparently healed state This healed state might last for years and then on some trifling cause suppuration might begin again and continue for another period of months or even years During the whole time beyond more or less deafness and discharge they experienced no inconvenience Many of them heard very well notwithstanding the suppuration and perforation while some of these patients regained excellent hearing and they were enabled to follow their business or profession by the use of an artificial pad of cotton It became a very serious question whether this class should be submitted to this extensive operation and up to quite recently it had not been suggested to interfere further with these

Mr A F CUMBERBATCH read a paper on the Selection of Suitable Cases for the Complete Mastoid Operation for the Cure of Chronic Suppurative Disease of the Middle Ear It was now he said much easier than it was some time ago to decide when it was advisable to expose the mastoid antrum and throw the iter attici and tympanum into one cavity for the cure of chronic suppurative disease of the middle ear Theoretically the operation should be performed in every case of chronic discharge in which all simpler means of treatment had been fairly tried and had failed For what length of time these simpler means should first be tried would depend largely on the temperament and experience of the surgeon and on the special conditions of the individual ear But although theoretically the question of an operation seemed easy enough to answer yet practically it was not so easy Hence in the present state of our knowledge it might be useful to mention certain groups of cases in which it appeared to him speaking generally that radical measures were either inexpedient or should not be undertaken too hastily First there was a group where the whole or greater part of the membrana tympani had been destroyed and the mucous lining of the tympanic cavity was greatly hypertrophied (polypoid in fact) but there was no obvious bone disease Secondly, there was another group in which there was frequent recurrence of the discharge on slight provocation although the discharge was on each occasion readily arrested Sometimes there was a permanent perforation of the membrana, in others the perforation closed as soon as the discharge ceased Thirdly there was another group where the question for or against an operation was a difficult one to decide and should not be too hastily answered in the affirmative These were cases of discharge from both ears in which the hearing was excellent and there were no symptoms calling for operative interference beyond the discharge There were on the other hand four groups of cases in which a complete mastoid operation should be performed (1) In cases of the second group in which the onset of the discharge was invariably preceded by malaise slight headache and rise of temperature and occasionally mastoid tenderness or discomfort (2) [illegible] ears which having given no trouble for many years comparatively suddenly developed marked symptoms of labyrinthine vertigo from which it was evident that either inflammation was spreading to the labyrinth or some accumulation was exerting undue pressure in that region, (3) cases of intermittent discharge where inspection of the meatus revealed masses of sodden epidermis, often hiding the presence of small granulations and where syringing constantly removed white shreddy patches the usual methods of treatment having failed to effect a cure and (4) cases of periodic attacks of mastoid pain commencing some time after all signs of active mischief in the ear had ceased and where, by excluding superficial neuralgia it was possible to determine that sclerosing ostitis existed The operation performed by Mr Ballance was so nearly perfect it seemed so easy in skilled hands it was so safe and the results were altogether so admirable that it was certain to widen the area of cases suitable for operation

The discussion on the subject was then adjourned to the next meeting of the society

MEDICAL SOCIETY OF LONDON

The Pathology and Treatment of Appendicitis

A MEETING of this society was held on Jan 22nd Dr F T ROBERTS the President being in the chair

A discussion on the Pathology and Treatment of Appendicitis was opened by a paper by Mr C B LOCKWOOD an abstract of which will be found on page 225

Dr W H ALLCHIN approached the subject from the aspect of treatment He referred to the time when the peritoneum was looked on with the greatest awe and the consequences of interfering with it were thought to be terrible At that time treatment consisted of an ill regulated expectancy in which the surgeon had very little or no part Now they had gone rather to the other extreme and the position taken by some was that the physician had little or no part in the management of appendicitis There were he thought four groups of such cases from a clinical point of view 1 There were the acute severe or fulminant cases attended by very little preliminary ill health The patient was suddenly taken ill with inflammatory symptoms and might die in a few hours These cases naturally came under the notice of the surgeon 2 Acute cases but less acute than the preceding First there were inflammatory symptoms lasting some days and then symptoms of abscess appeared These also came naturally within the domain of the surgeon 3 Subacute cases These came more commonly within the knowledge of the physician He had seen more of these cases in females The course of such cases lasted some 12 or 14 days In these there were pain, tenderness, and might be a swelling in the inguinal region, and vomiting general disturbance of health and some elevation of temperature These cases formed by far the largest group Their natural tendency was to comparative cure At least the patients went out and passed away from observation These were the cases which called for medical treatment and he thought immediate operation was a mistake A notable feature of these cases was the variation from day to day in the symptoms and in the size of the swelling 4 There were the relapsing cases cases with recurring attacks of varying severity at varying intervals In any case they must make up their minds that it was impossible to lay down hard and fast rules In the first two groups and whenever unmistakeable signs of suppuration were present the treatment must be surgical but the third group might or might not be handed over to the surgeon Of the various symptoms Dr Allchin attached most importance to an increase in the rate of the pulse both for the purposes of prognosis and the diagnosis of the actual process which was going on As to the treatment of this group rest and relief of the bowels by simple enemas or salines were the chief points He had found no occasion to regret the administration of small quantities of opium in such cases This statement was perhaps heretical but he regarded it as beneficial to the patient and indicated by the pulse and other symptoms This might be supplemented by belladonna and perhaps hot fomentations to the iliac fossa The relapsing cases offered considerable difficulty in treatment and in such cases the greatest good might be done by the surgeon though he did not [illegible] rules had been laid down Each case must merits. Many of these cases also benefited by rest and medical treatment.

Mr. **ARTHUR BARKER** referred to the transfer of the septic organisms through the lymphatic spaces to other parts. Mr. Lockwood had offered an explanation of those difficult cases in which although they appeared to be non-suppurative an abscess would be found behind the cæcum. The appendix in such cases appeared normal to the naked eye. Other cases of extensive cellulitis and even subphrenic abscess following appendicitis might be similarly explained. He would like to draw attention to the power of the peritoneum to control what he might call the ravages of the bacteria. They ought to bear this in mind in surgical treatment, especially in dealing with the omentum and in connexion with the question of washing out His view was that the peritoneum had more bactericidal power than was generally believed. Consequently he was not in the habit of washing out the abdomen excepting in rare cases. He was inclined to agree with Dr. Allchin in his use of opium He believed it was, in small doses, very beneficial. He thought a good many cases could be left to the physician. He had seen many cases where conservative measures had been attended by the best results, but, on the other hand, he remembered one case with very few symptoms in which he found a large concretion loose in the abdominal cavity.

Dr. **F. J. SMITH** remarked that perforation of the appendix was strictly comparable with certain cases of perforating ulcer of the stomach. In both diseases perforation might not be preceded by any notable symptoms. A gangrenous appendix might be found without any preceding pains or other symptoms. As to washing out the peritoneum, he thought it was very difficult to cleanse the peritoneum by washing it. If there were obvious signs of suppuration the surgeon must be called in, but the difficulty often was to make out for certain whether there was pus or not. The rapidity of the pulse was useful and he had been accustomed to rely also on the occurrence of night-sweats. He thought that the commonest anatomical position of the appendix was that of being tucked up at the back of the ascending colon.

The discussion was then adjourned until the meeting of the society on Feb. 24th.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Bacteriological Diagnosis in School Epidemics of Diphtheria.

A MEETING of this society was held on Jan. 19th, Dr. **H. F. PARSONS**, the President, being in the chair.

Mr. **KENNETH W. GOADBY** read a paper upon the Utility of Bacteriological Diagnosis in a Diphtheria Epidemic in a School. In the winter of 1898–99 an outbreak of sore-throat culminating in diphtheria occurred in the Poplar Union Schools at Forest-gate. The schools belonged to the class known as "barrack schools" and were occupied by some 600 children. From March to October, 1898, 27 cases of scarlet fever occurred, and 17 between Nov. 27th and Dec. 31st. On Dec. 15th an epidemic of sore-throat commenced, following three cases of diphtheria in November, and five more appeared during December. On Jan. 21st a bacteriological examination was undertaken and the whole of the 586 children present in the school were examined in the course of six days. The method adopted was the usual one of cultures in tubes of coagulated blood serum from sterile cotton-wool swabs which had been passed over the pharynx and fauces. These were incubated at 37 5° C. for 24 hours and the resulting growths examined by means of coverslip preparations stained with methylene blue. Of the 586 children examined 190 showed the bacillus of diphtheria and 99 that of Hofmann, giving a percentage of 34 1 per cent. of children with the Klebs-Loffler and 16 9 with Hofmann's bacillus. The morphology was relied upon for diagnosis as it was obviously impossible to inoculate animals with all the cultures. The microscopical appearance of the bacillus diphtheriæ as given by Washbourn and Garratt[1] and Eyre[2] was that accepted. Meade Bolton[3] had stated that of 214 healthy persons previously exposed to infection from diphtheria 45 5 per cent showed the Klebs-Loffler bacillus. Park and Beebe examined the throats of 48 apparently healthy children in 14 families in which diphtheria was present, and in 50 per cent. found the bacillus diphtheriæ. Müller examined bacteriologically 100 children in the general wards of the Charité in Berlin; of these six on entry had the bacillus in their throats without exhibiting any of the signs of the disease. Two days later the bacillus had appeared in 14 others. Many other observers had made similar observations and in most cases the number of infected individuals was large. From November, 1898, to the time the examination was made 21 cases of clinical diphtheria occurred in the schools. After the examination the children were isolated; those showing the diphtheria bacillus were kept in one part of the school, the unaffected ones being confined to another part. School was stopped and all indoor gatherings except at meal-times were also suspended. The two classes of children were kept at opposite ends of the dining hall; all the plates, knives, &c., were boiled after use. Owing to the structural arrangements of the school, its many intercommunicating passages, and other practical difficulties, the isolation broke down, notwithstanding which the number of cases of clinical diphtheria, as well as those of sore-throat, at once declined, so that in February there were only five cases of diphtheria. In March another examination of 50 children, taken at random from the presumably unaffected, was made, with the result that some 30 per cent. were found to have the diphtheria bacillus in their throats. Under these circumstances the school committee decided to again mix the children so that the suspended school duties could be resumed. 18 children were examined before the mixing took place and found to be free from the specific bacillus. 10 days after the resumption of school work the same 18 children were re-examined and it was found in six of them. At the same time the number of sore-throats, as well as cases of clinical diphtheria, again increased for a time. Thus in March there was only one fresh case of true diphtheria but in April nine, and of sore-throats nine were observed during March, whereas in April there were 19. In February seven children who had been at a convalescent home were re-admitted to the school and placed among those supposed to be healthy; of these, three developed diphtheria in a severe form—in fact, these three were the most serious in the whole epidemic. On June 21st 90 children were again examined and 27 7 per cent. presented the diphtheria bacillus, whilst on Sept. 29th 50 children examined showed a percentage of 30 with bacilli in their throats. Another school was also examined for control purposes. In this school no diphtheria had been observed for two years. Of 100 children examined 18 showed diphtheria bacilli. The clinical condition of the throats was also noted when the examinations were made, and in the infected school the number of unhealthy throats was found to be very large; at the infected school out of 586 children 262 had enlarged tonsils, 161 some grade of hyperæmia, and 35 some exudation on the fauces. At the control school in 100 children 31 showed enlarged tonsils and 11 hyperæmia, but none of them had exudation. Of the several classes the children with enlarged tonsils showed the largest number affected with the bacillus diphtheriæ; thus in the Forest Gate School 148 out of a total of 190 children in which the bacillus was found were suffering from some throat affection and 90 of the 148 had enlarged tonsils. In the control school 41 had some unhealthy condition of throat, and of the 18 in which the bacillus was found 14 belonged to the children with unhealthy throats, nine of these having enlarged tonsils. With regard to the source of infection the milk was examined and found to contain virulent diphtheria bacilli, the organisms isolated in pure culture killing guinea-pigs in 48 hours. The water was also examined but with a negative result. The treatment of the children adopted was the spraying of the throats with a 2 per cent. solution of lysol night and morning, any suspicious throats being sprayed with a 0 5 per cent. solution of formalin. The school had been free from diphtheria from September, 1899. A large Aymard's steriliser had been put up and working since June with excellent results, and it was an interesting fact that since the milk-supply had been sterilised there had been no cases of summer diarrhœa in the school, though there was a considerable amount in the district around. The conclusions arrived at were that bacteriological examination of the children followed b rigid isolation of those shown to have the specific bacillus in their throats was the proper method to adopt in scho epidemics of diphtheria; that milk sterilisation should always be carried out with the whole of the supply, no portion being retained for the use of anyone in the institution (at Forest Gate the officers' portion was taken before the milk was boiled); that the method of sampling probably gave a sufficiently reliable result to determine the progress of the epidemic; and that the unhealthy conditions, especially hypertrophy of the faucial mucous membrane, was a very large factor in the persistence of the diphtheria bacillus in the throat.

[3] Medical and Surgical Reporter, 1896.

The SECRETARY, in the absence of Dr. F. H. BERRY (Watford), read a paper narrating a similar experience at the London Orphan Asylum. Here the 350 boys and 200 girls had little intercourse with the outer world except during the Christmas and midsummer holidays and were kept entirely apart, never seeing one another but in the dining hall and the chapel, where they were separated by wide gangways. The cases occurred among the girls only, though the milk-supply was the same. There had been no outbreak of diphtheria, and few if any cases for many years, when in January, 1898, after the holidays several cases of feverish follicular tonsillitis appeared. On Feb. 25th a case of diphtheria was noticed so typical that antitoxin was at once used before the Klebs-Löffler bacillus had been demonstrated. A series of mild sore-throats was followed on March 27th by a case of diphtheria (clinical and bacteriological) and three sore-throats with the Klebs-Löffler bacillus which were at once isolated. A succession of "throats" lasted until April 30th when after an interval of a week four cases of typical diphtheria and three suspicious throats, one of which developed into diphtheria, occurred between May 7th and 10th. All the cases were of a severe type, but being treated promptly with antitoxin made rapid recoveries. It was then resolved to isolate all children with sore-throats in a vacant house in the grounds, but since these numbered 76 and the accommodation was not sufficient for more than 50 they were divided into dark red and pale red throats; the former, as presumably the worst, were isolated and the latter were sent back to the school. Dr. Washbourn was then asked to examine the whole of the girls and the resident mistresses whose throats presented anything amiss. These were 142 in number, eight being mistresses. Diphtheria bacilli were found in those of three mistresses and 14 girls and Hoffmann's in 33. Two of the mistresses were teachers of music who gave their lessons in glass-walled compartments just large enough to hold the piano, teacher, and pupil, which might have assisted in the spread of the infection. All who, though not ill enough for the infirmary, presented the Klebs-Löffler bacillus were detained in the isolation building for a fortnight, their throats being sprayed with a disinfectant night and morning. A fresh examination showed that only two—one mistress and one girl—were still infective, and these after another week's treatment were pronounced free and no more sore-throats appeared in the school from that time or indeed from the exclusion of those in whom the Klebs-Löffler bacillus was found.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Fœtid Expectoration.—Removal of a Submucous Fibroid by Section of the Uterus.—Volvulus associated with Hernia.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 12th, Dr. A. G. BARRS, the Vice-President, being in the chair.

Dr. STANLEY DODGSON related the case of a woman, aged 30 years, who had Cough, Fœtid Expectoration, and Occasional Hæmoptysis. The disease was of seven months' duration and dated from an extraction of teeth under ether. The patient had a temperature of 102° F. and was expectorating about 20 ounces of fœtid sputum daily. The only physical sign was impairment of resonance at the left base. Creasote inhalations on alternate days were given for two months, at the end of which time the temperature was normal and the cough and foul expectoration had disappeared, while the patient had put on weight. The patient had remained in good health during the three succeeding months.—A discussion followed in which Dr. H. J. CAMPBELL, Dr. C. M. CHADWICK, Dr. E. SOLLY, Dr. E. F. TREVELYAN, and Dr. A. G. BARRS took part. The chief points raised were (1) the value of creasote given by the mouth as against the so-called creasote chamber; and (2) the difficulties of diagnosis in some cases of fœtid expectoration.—Dr. STANLEY DODGSON replied.

Dr. J. BRAITHWAITE read a paper on the Removal of a Sub-mucous Fibroid by Section of the Uterus. As the case was possibly the first in this country in which the uterus had been opened by what might almost be called Cæsarean section for the removal of a contained tumour it was of some interest. The patient was 41 years of age, a nullipara, and had suffered from exhausting hæmorrhage. The cervix was extraordinarily rigid and could only be dilated by means of Reid's screw dilators under ether. It was then possible to reach an internal fibroid near the fundus. The fibroid was probably not larger than a big horse chestnut, but it was impossible to remove it even *morcellement* as the vagina was very small and the cervix was rigid and undilatable. On Dec. 29th last it was removed by making a central incision in the anterior wall of the uterus, hæmorrhage being prevented by a rubber tourniquet round the cervical end. The tumour was easily turned out of the uterine cavity with its mucous covering entire. The cavity was drained by a tube into the vagina. The wound in the uterine wall was brought accurately together with catgut sutures, about three to the inch. The abdominal wound was closed with sutures in three layers as usual, the peritoneal and middle layers with catgut, and the skin with silkworm gut. The patient made an uninterrupted recovery. It would be noticed that this was not abdominal section and enucleation of fibroids in or on the uterine wall—a subject upon which various papers of great interest had been published.—Dr. E. O. CROFT and Dr. J. B. HELLIER made some remarks and Dr. BRAITHWAITE replied.

Mr. LAWFORD KNAGGS read a paper upon Volvulus in Association with Hernia. Four distinct groups could be recognised: (1) cases in which the neck of the volvulus was within the sac or close to the ring; (2) cases in which the hernial contents were implicated in the volvulus but where the neck and some of the affected coils lay within the abdomen; (3) cases in which the volvulus was produced within the abdomen upon the reduction of the hernia; and (4) cases in which a volvulus occurred within the abdomen from some predisposing condition more or less directly connected with a hernia. All these groups possessed features of much interest, but Mr. Knaggs only dealt with the second group in which the cases were of unusual gravity and importance.—Mr. H. LITTLEWOOD discussed the paper and Mr. KNAGGS replied.

The following cases and specimens were exhibited:—

Dr. EDWARD WARD: (1) Ruptured Spleen and Kidney; and (2) Ovarian Tumour.

Dr. A. G. BARRS: (1) Specimen of Amyotrophic Lateral Sclerosis; (2) Cancer of the Liver; and (3) a case of Hydro-pneumothorax with Typical Succussion Splash.

Mr. W. H. BROWN: (1) Mediastinal Growth; (2) Unusual Fracture of the Clavicle; and (3) Rupture of the Common Femoral. The patient in this case was shown.

Dr. J. B. HELLIER: Carcinomatous Uterus removed per vaginam.

Mr. H. LITTLEWOOD: (1) A case of Suprapubic Lithotomy with Prostatectomy in a patient, aged 70 years; (2) a case of Compound Depressed Fracture of the Skull in which the patient had been violent and delirious for a month; and (3) Tonsil and Glands removed for Squamous Epithelioma.

Dr. GORDON SHARP: Four cases illustrating the After-effects of Diphtheria.

Mr. B. G. A. MOYNIHAN: A case of Extensive Tuberculous Disease of the Ankle and Foot treated by Iodoform Injection.

Dr. E. F. TREVELYAN: Specimen of Hæmorrhage into the Pons causing sudden death.

Mr. MAYO ROBSON: (1) Adenoma of the Small Intestine causing Intestinal Obstruction; (2) Sarcoma of the Soleus Muscle; and (3) Tuberculous Kidney.

Mr. LAWFORD KNAGGS: Case of Erasion of the Ankle for Tuberculous Disease by Four Vertical Incisions (Clutton's Method).

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Salol in the Treatment of Small-pox.—Permanent Dislocation of the Patella.—Murder and Suicide by Cut Throat.

THE fourth ordinary meeting of this society was held on Jan. 17th, Mr. ALEXANDER MILLER, the President, being in the chair.

Dr. Norman Walker showed a man suffering from Acne Varioliformis which had lasted for two years. The disease, as it has been described, extended into the hair as true acne very rarely did. The scarring was exactly like that seen after small-pox. The patient had no syphilitic lesions and though the condition had improved under the administration of iodide of potassium Dr. Walker did not think that that disease was due to syphilis.

Dr. C. W. MacGillivray showed a boy who had been Struck over the Left Parietal Bone by a piece of lead piping which had fallen from a height of about 30 feet. The wound was examined five hours after the injury and a piece of the left parietal bone of about the size of a small oyster-shell was found entirely loose in the wound; this was removed, leaving an area of about two and a half square inches of the dura mater exposed. The boy was never insensible and the wound healed perfectly without any febrile disturbance.

Dr. Charles Begg communicated a paper on Clinical Experience with Salol in the Treatment of Small-pox. He narrated his experience of the disease in China and thought that an explanation of the value which salol had had in his hands might be of value in view of the late spread of the disease in England. Dr. Begg was not aware of any similar observations to his own. The following case led him to think of the use of salol in small-pox. A patient who suffered from cystitis was taking a drachm of the drug daily. This individual had previously suffered intensely from the bites of mosquitoes. When taking salol a slight mental depression showed itself and the man did not even notice the mosquitoes. He had hundreds of bites, yet none of these showed the least appearance of swelling, redness, or irritation. This led Dr. Begg to think that salol might be useful in other irritating skin affections and on trying the drug its anæsthetic action was confirmed. Dr. Begg did not think that the mental depression which salol produced had anything to do with this sedative action on the skin. The drug was next tried in cases of small-pox and was found to keep the patient free from all irritation. There was no desire to scratch the skin and so the danger to the eyes was greatly avoided. This freedom from cutaneous irritation allowed of the patient sleeping and consequently exhaustion was prevented. Salol also almost always prevented the vesicles from maturing into pustules. Nearly all vesicles ended as such. In one case, that of a European, who had only been once vaccinated in infancy, confluent small-pox occurred and only two groups of vesicles ended as pustules. In almost every case the lymph dried up and the eruption so ended. No dangerous effects from the use of the drug in daily doses of one drachm continued for a long period manifested themselves. The cases should be brought at an early period fully under the action of the drug, and when properly so treated little scarring resulted. The foul odour which small-pox patients exhibited was entirely masked by the fruity odour which the drug manifested during its elimination by the skin.—Dr. Norman Walker stated that his experience in the treatment of skin diseases by salicine agreed with the observations of Dr. Begg and he thought that the absence of scarring was due to the non-formation of a hard scab and that the prevention of suppuration in the pocks accounted for this.

Mr. Shaw McLaren communicated a paper on Permanent Dislocation of the Patella. He said that the dislocation was a displacement of the patella outwards so that it lay even in extension generally to the outside of the median line, while in flexion it slipped outwards and backwards until it lay on the outer surface of the external condyle, its anterior surface being directed to a certain extent outwards The gait was thus rendered most insecure and the patient frequently fell, and attacks of synovitis were not infrequent. Mr. McLaren agreed with Appel that the condition was really a congenital defect, a deformity of the external condyle and trochlea of the femur, though a fall might first call attention to the malformation. In most of the recorded cases it had been noted either (1) that the deformity was actually present at birth; (2) that the child learnt to walk at a late period or walked insecurely during later years; (3) that there was rickets; (4) or genu valgum; (5) or outward rotation of the leg; (6) or ill-developed patella; or (7) abnormal shape of the external condyle and patella fossa of the femur. A case which he had met with was briefly as follows. It was that of a woman, aged 19 years, who had never walked securely and did not really walk alone until the age of seven years. She could never run, was always falling, and had knock knee on the left side. She had presented evidences of rickets in childhood. On the left side there was marked genu valgum, the leg being rotated outwards. When the knee was extended the patella lay to the outside of the normal position; when the joint was flexed it passed further and further out until it lay on the outer side of the external condyle. The fossa patellæ of the trochlear surface of the femur could be felt to be partially filled up on its outer side as if the external condyle projected into it, while the outer edge of that condyle seemed to be entirely wanting. Mr. McLaren related the notes of Appel's two cases and also several other cases which were not noted by him. The quadriceps, in passing from its origin to its insertion, formed an obtuse angle at the point of which the patella lay. During action the patella would be pulled outwards unless this were prevented by the prominence of the external condyle, which kept the patella in the middle line. If the fossa patellæ were too shallow or the ridge of the external condyle was not prominent enough the patella would lie dangerously far out on the trochlea. A slight accident or a severe contraction of the quadriceps was only necessary to shoot the patella off the front of the condyle altogether. In those cases where the condyle was markedly deficient the complete dislocation might exist from birth or very early life. In any case, the structures on the outer side of the patella contract eventually and prevent the bone retaining its proper position. As regards treatment, various methods which had been adopted by different operators were related. The method which Mr. Shaw McLaren adopted in his case consisted in liberating the patella by dividing on the outside whatever contracted structures prevented it from assuming its normal position and then mooring it there by sutures passed through its inner border. Four years after the operation the patella had retained its position slightly external to and higher up than normal, and the patient walked and went up and downstairs easily and could also now run. This method of treatment seemed rational and effective and in most cases ought to be successful. The severer operation of opening the joint and enlarging the groove for the patella might be necessary in some cases, whilst transplanting the ligamentum patellæ inwards should be reserved for those cases where there was a high degree of outward rotation of the leg.—The President, Dr. MacGillivray, and Mr. Caird having spoken, Mr. McLaren replied.

Dr. Harvey Littlejohn narrated an interesting case of Murder and Suicide by Cut Throat, showing how such cases ought to be investigated and the difficulties to be encountered in their elucidation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Deciduoma Malignum.—Ulceration in the Female Urethra.

A meeting of this section was held on Jan. 5th, Dr. A. V. Macan, the President, being in the chair.

Dr. W. J. Smyly read a paper on Deciduoma Malignum. Having reviewed the literature of the subject he said that observers were now almost unanimous in believing that this was a disease sufficiently distinct to merit separate consideration. They also agreed as to its clinical features, pathological appearances, and treatment; also as to its connexion with pregnancy, and differed only as to their views concerning its histogenesis. He inclined to Veit's opinion that the disease was a sarcoma, modified by pregnancy. He also described a case which had come under his own observation. The patient, a pluripara, was delivered of a hydatiform mole in December, 1898. She had repeated hæmorrhages until May 10th when she had so profuse a hæmorrhage that she was reduced to a condition of profound anæmia. The uterus was dilated and a quantity of material resembling placenta was removed which on microscopical examination proved to be deciduoma malignum. Putrefaction and septic fever followed with pulmonary symptoms and empyema preceding radical measures. She lingered two months and then died. There was no post-mortem examination. Dr. Smyly showed the microscopical specimens at the Edinburgh meeting of the British Medical Association, when they were pronounced by Dr. Sänger to be typical examples of the disease which he had described.—Dr. R. D. Purefoy, Dr Smith, and the President discussed the case.

Dr. PUREFOY read a paper on a case illustrative of a rare form of Ulceration in the Female Urethra. He said that the close resemblance in aspect and clinical history between some forms of chronic syphilitic disease and others of a malignant nature had long been recognised—indeed, sometimes the effect of treatment by drugs must be observed before the differential diagnosis could be safely established. Especially was this observable in regions where cutaneous and mucous structures coalesced and hence the external female genitals, as might be expected, furnished some of the best illustrations of this fact. A young woman who recently was under treatment in the gynæcological wing of the Rotunda Hospital complained of pain and soreness in the vagina and on examination the following conditions were observed. The greater labia were of normal size and healthy. On the inner surface of the left nympha a circular excavation existed, the edges were sharp-cut and overhanging; the base, white cicatricial tissue. The entrance of the vaginal canal was closed by a morbid growth with nodulated surface of a deep red colour which on close examination proved to be an outgrowth hanging from the edge of an enormously dilated urethra; indeed, the lower third of this passage was so widened and distorted that considerable difficulty was experienced in passing a catheter into the bladder. Strange to say, the patient in spite of this did not suffer from incontinence of urine. In the vestibule and adjoining parts an indolent shallow ulceration was observed, alternating with patches of white cicatricial tissue marking its former course. In the writings of the late Dr. West cases closely resembling, if not identical with, the one under consideration were recorded. He said: "The affection has come six times under my observation—twice in married women who acknowledge to having suffered from venereal disease and four times in women of unchaste life, one of whom was at the time suffering from a secondary syphilitic eruption. The ulceration appears to begin at the orifice of the urethra, extending thence inwards towards the bladder, producing in its course a great widening of the canal and a patulous condition of its orifice, so that the finger-tip can easily enter it." Dr. Purefoy said that in its earlier stages this distressing affection admitted of some amelioration by local measures—the application, for instance, of oxide of zinc in the form of ointment, or lotion with liquor plumbi; and, even in the advanced stage, attended with widening of the urethra, the use of strong nitric acid, or the actual cautery, might bring about such cicatrisation and attendant contraction of the diseased parts that control of the bladder might be regained. Some facts in the history of his patient, as well as some scaly patches on the face and neck, afforded such presumptive evidence of a syphilitic taint that a combination of bichloride of mercury and iron in mixture was prescribed for her, and its use was followed by improvement. In many points these cases bore a close resemblance to that formidable disease of the female genitals first described in 1849 by M. Huguier, and to which he gave the name "lupus hypertrophicus or perforans." This affection was very rare; medical literature did not afford records of more than about 40 cases in all. Illustrations of some of them would be found in Dr McClintock's "Memoirs on Diseases of Women."—Dr SMITH and the PRESIDENT discussed the paper.

Dr. PUREFOY showed a case of Ectopic Gestation removed by Vaginal Cœliotomy.

FORFARSHIRE MEDICAL ASSOCIATION.—A clinical evening of this association was held in University College, Dundee, on Jan. 10th, Dr C. Templeman, the Vice President, being in the chair.—Professor J. A. C. Kynoch showed a child from whom he had removed a Renal Sarcoma three years before by Laparo-nephrectomy. Six other cases of laparo nephrectomy on children under two years of age had been reported as alive and well three years after operation. There was still considerable difference of opinion in regard to the pathology of these renal tumours. Although only 5 per cent. of all reported cases had recovered the chance of a cure ought to be offered.—Dr. R. C. Buist and Dr C. McVicar also spoke.—Dr. A. McGillivray showed (1) a boy with Rupture of the Choroid and (2) a patient who after injury had suffered from a Dilatation of One Pupil which he was inclined to consider as due to irritation—an irritation mydriasis.—Dr. McVicar showed a patient with a large Cystic Swelling which extended from the anterior border of the sterno-mastoid to the middle line with branching processes under the same muscle and up into the floor of the mouth. The fluid was viscid and clear and when it escaped by the mouth had a sweetish taste. It appeared to be a bronchial cyst and was of interest as such cases had been known to assume an epitheliomatous character.—Dr. J. Gray showed for Professor McEwan specimens of (1) Fracture, Base of the Skull; (2) Epithelioma, Tongue; and (3) Limb from a case of Senile Gangrene.—Dr. Gray showed a cast of an Arm with Lipomata.—Professor Kynoch illustrated by a painting an unusual Pigmentation of the Central Linear Cicatrix as well as the Stitch Scars of a case of Ovariotomy which he had performed during pregnancy. A scar of two years' duration on the breast had remained unaffected. He asked whether the condition was due to the ovariotomy or to the delicate skin, and in relation to this mentioned that Bloxall had reported a case in which the scar left after removal of a dermoid had become pigmented during a subsequent pregnancy.—Dr. Buist had seen a like scar pigmentation during a pregnancy following immediately after the removal of one ovary.—Professor Kynoch showed a Multilocular Ovarian Cyst and remarked on the few adhesions present notwithstanding the fact that part of the cyst had been ruptured by an accident some time previously.—Professor Marshall and Dr. Buist added some comments.—Dr. McVicar showed (1) an Ovarian Cyst which in view of the clinical history and the naked-eye and microscopic appearance seemed to be an abscess of the ovary; and (2) a Vermiform Appendix with the Lumen practically Occluded.—Dr Buist and Dr. Kynoch discussed some of the points raised.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Jan. 17th, Mr. W. Thorburn, the President, being in the chair.—Mr. F. A. Southam showed two specimens of Papilloma of the Bladder which had been removed by suprapubic cystotomy from male patients, aged 45 and 64 years respectively. In both cases the only symptom was a painless hæmaturia, in one instance continuous and in the other intermittent. The patients made a good recovery from the operation and in both instances the removal of the growth was followed by a complete cessation of the hæmaturia.—Dr. Warrington described the case of a man, aged 60 years, who had suffered from Anæmia. His condition gradually got worse and he developed kyphosis of the vertebral column; spontaneous fracture of the ribs also occurred. The urine contained large quantities of the body known as albumose which was first described by Bence Jones in 1848. The necropsy showed that the ribs were remarkably affected, the bony substance being reduced in thickness to about that of a sheet of notepaper, while their lumen was filled with a reddish mass similar in appearance to splenic pulp. The sternum and vertebræ showed a similar condition; the substance present in the bones of the thorax also gave the reaction of albumose.—Dr. Craven Moore showed a series of specimens illustrating the various types of Lymphadenoma and briefly referred to their morbid relations.—Dr. W. E. Fothergill described examples of Exomphalos and Pseudo anencephalus.—Other preparations were shown as Card Specimens.

HARVEIAN SOCIETY OF LONDON.—The annual meeting of this society was held on Jan. 18th.—Mr Thomas Bryant was elected an honorary member of the society to fill the vacancy caused by the death of the late Sir James Paget.—The report of the council and the treasurer's statement were read and adopted.—The election by ballot of the officers for the ensuing year resulted as follows:—President: Dr. W. H. Lamb. Vice Presidents: Mr. Peyton Beale, Dr. W. J. Gow, Mr. Alban Doran, and Dr. Winslow Hall. Treasurer: Mr. Edmund Roughton. Council: Mr. Buckstone Browne, Dr. H. A. Caley, Mr. Jackson Clarke, Dr. A. Eddowes, Dr. J. F. Goodhart, Dr. Leonard Guthrie, Mr. H. E. Juler, Dr. H. J. Macevoy, Mr. Sefton Sewill, Dr. G. A. Sutherland, Dr. Herbert Spencer, and Dr. Atwood Thorne.—The retiring President (Mr. H. E. Juler) delivered an address on the Value of the Observation of Eye Symptoms in relation to General Medicine and Surgery.—A vote of thanks to the retiring President for his address and for his services to the society was proposed in very genial terms by Mr. Henry Power and carried with acclamation.—Votes of thanks [illegible] retiring Vice-President (Dr. Ernest Gi [illegible] and to the retiring Secr [illegible] proposed by Mr. Edward B [illegible] The meeting [illegible] largely attended. Instrumental music was provided by the string band of the Royal Horse Guards.

MANCHESTER MEDICAL SOCIETY.—The following gentlemen were elected office-bearers for the year 1900:—President: Dr. T. C. Railton. Vice-Presidents: Mr. W. Coates, Dr. A. Donald, Dr. W Milligan, and Dr. R. Wild. Treasurer: Dr. C. E. Glascott. Secretary: Dr. E. S Reynolds. Committee: Dr. W. H. Brazil, Dr. E. M. Brockbank, Dr. J. G. Clegg, Dr. J. J. Cox, Dr. T. Harris, Dr. M. P. Ledward, Dr. F. C. Moore, Dr. J. E. Platt, Dr. C. Skinner, Dr. G. Thomson, Dr. R. T. Williamson, and Mr. A. Wilson. Library Committee: Dr. T. N. Kelynack, Dr. A. Lea, and Mr. J. W. Smith. Auditors: Mr. J. H. Ray and Dr. W. K. Walls.

BRADFORD AND DISTRICT MEDICO-ETHICAL SOCIETY.—The annual general meeting of this society was held on Jan. 17th. The officers elected for the ensuing year were as follows:—President: Dr. J. H. Bell. Vice-President: Dr. D. Goyder. Honorary treasurer: Dr. F. K. March. Honorary secretaries: Dr. W. Horrocks and Dr. A. Manknell. Committee: Mr. I. Mossop, Dr. W. Parkinson, Dr. A. Bronner, Mr. J. Harrison, Mr. W. Handcock, and Dr. J. Metcalfe. Auditors: Dr. W. Arnold Evans and Dr. E. G. Peck.

Reviews and Notices of Books.

The Pathologist's Handbook; a Manual for the Post-mortem Room. By T. N. KELYNACK, M.D. Vict, M R.O.P. Lond. 126 Illustrations. London: J. & A. Churchill. 1899. Pp. 186. Price *4s 6d.*

THIS is an excellent little book, although possibly its title conveys the idea that the work deals with more than it actually does, but, as Dr. Kelynack states in his preface, "My main object has been to indicate methods. Reference to special lesions has, to a very great extent, been omitted. For descriptions of these the student will naturally refer to his text-books on Morbid Anatomy." Dr. Kelynack also claims to have merely "attempted to furnish a concise guide for students acting as clerks in the post-mortem room and a suggestive manual for junior practitioners." These excerpts from the preface give a very fair idea both of what the book is and of what it is not.

Chapter II., "General Considerations," deals in a very clear and sensible manner with such subjects as the prevention of post-mortem wounds, the cleansing of the hands, and the question of permission from the relatives. With regard to this latter point Dr. Kelynack remarks: "If what may be termed the æsthetic or sentimental side of the question were more generally attended to it is very probable the public would soon show less repugnance to the holding of pathological examinations. The care of a mortuary is a matter of real importance. Every hospital should have a mortuary chapel with suitable arrangements for the viewing of the corpse by the friends." In this we quite agree, and the strictures upon the condition of mortuaries apply not only to those attached to hospitals but to many parochial buildings, though there are honourable exceptions, notably in the case of Westminster, Chelsea, and Kensington. Dr. Kelynack gives a caution as to the taking of notes in a post-mortem examination for medico-legal purposes. These notes, he says, should indicate pathological facts and give full descriptions of lesions observed, but no opinions or inferences should be expressed. This is an important point which is often neglected. Another practice to which Dr. Kelynack alludes is noteworthy. "In cases likely to lead to litigation I have generally found it wise to ask all the medical men present to sign the report in evidence of their agreement with the facts therein stated. Their opinion as to the cause, nature, and general bearing of the case is thereby not interfered with, and much of the quibbling as to the facts which tend to make medical men ridiculous in the eyes of the public may be avoided." It is always as well in a medico-legal case for a second medical man to be present, and if this precaution were taken such lamentable errors as occurred in a recent case would never happen.

Chapter III. deals with Instruments, and Chapter IV. with the External Examination. The latter chapter contains a useful table indicating the differences between post-mortem staining and ante-mortem contusions.

Chapter V. contains the consideration of the Internal Examination, and here again a useful note of warning is sounded against the confounding of post-mortem changes with true morbid conditions.

Chapter VI. deals with the Thorax and Neck, Chapter VII. with the Abdomen, and Chapter VIII. with the Head and Spine. Chapter IX. deals with Special Examinations, including a note upon examinations conducted in private houses, and Chapter X. is concerned with medico-legal matters, such as exhumation, poisoning cases, death certificates, inquests, and the like.

Chapter XI., entitled Miscellaneous Considerations, treats of the "restitution" of the body, post-mortem records, and one or two other points. There is only one point on which we would make a suggestion and that is that in a future edition the operator should be advised, if the costal cartilages are calcified, to fold the soft tissue of the chest wall over them before putting his hands into the thorax. Such a procedure will save many a troublesome scratch. It is a small point but one which we have often seen neglected and Dr. Kelynack does not mention it. The book certainly on the whole is worthy of great praise.

Lehmann's Medicinische Hand Atlanten, Band IX. *Atlas of the Nervous System in Health and in Disease, exhibiting the Groundwork of its Anatomy, Pathology, and Therapeutics.* By Dr. CHRISTFRIED JAKOB, of the University of Buenos Ayres, with a Preface by Professor Dr. A. von STRUMPELL. Second Edition, thoroughly revised, with 84 Plates and 208 pages of Letterpress. München: J. J. Lehmann. 1900. Small octavo. Price *14s.*

THOSE who purchase this work must not expect to obtain a series of plates giving the distribution of the cranial or spinal nerves. It does not contain any account of the fifth or seventh nerves, nor are there any drawings of the branches of the brachial or lumbar plexus, but to those who know how to use it it will prove, we are assured, a very valuable treatise and book of reference. It commences with ten excellent coloured plates of the brain exhibiting its superior, lateral, median, and inferior aspects, the appearances presented on transverse sections of the brain at successive planes, and different views of the cerebellum. The plates are not spoiled by figures, lines, or letterpress, but an outline drawing is placed on the opposite page, which is lettered, and there is a page of references. The next plates show the relation of the white and grey substances on section of the crus cerebri and medulla oblongata and in photographs of the cord in the cervical and lumbar regions. Two plates are devoted to the embryology of the nervous system. The glia and ganglion cells and the production of the neurons as processes from the cells are next depicted. Then follow a drawing showing the arrangement of the cells in the cortex cerebri, a plate with the disposition of the convolutions, others showing the position of the nuclei in the medulla oblongata, and the structure of nerve fibres and their appearances in health and disease. The twenty-sixth plate exhibits in different colours the columns of the cord. The general arrangement of the cerebro-spinal nerves is next illustrated. Many plates follow with for the most part two and three figures on each plate, which are coloured and show the arrangement of the fibres in different parts of the brain, medulla oblongata, and spinal cord, as in sections made through the corpus callosum, the corpus striatum, optic thalamus, and olive. Anyone who will study these drawings carefully will make himself master of the structure of the brain and the course of the fibres in the spinal cord in a way that would require many dissections and the consumption of much time to accomplish. The last 20 plates are chiefly occupied with illustrations of the effects of disease on the nerves and nerve-centres; such, for example, as neuritis multiplex, tabes dorsalis, syringomyelia, and various forms of ascending and descending degeneration. There are between two and three hundred drawings altogether, and they are very instructive. In the text which accompanies the plates no attempt is made to give a description of the nervous system as a whole, but those who are able to read German will find that the author has been able to condense into a small space much useful information in regard to the functions of the several parts of the nerve centres and the effects of disease. The work is very well produced, and considering the number and excellence of the illustrations its cost is surprisingly small.

Recherches Cliniques et Thérapeutiques sur l'Epilepsie, l'Hystérie, et l'Idiotie. Par BOURNEVILLE, avec la collaboration de MM. CESTAN, CHAPOTIN, KATZ, NOIR, PHILIPPE, SEBILLEAU, et BOYER. (*Clinical and Therapeutical Researches on Epilepsy, Hysteria, and Idiocy.*) Vol. XIX. Large 8vo. *Paris: Aux Bureaux du Progrès Médical et Félix Alcan.* 1899. Pp. 236, with 13 Figures in the text, and 13 Plates. Price 5 francs.

THIS volume contains an account of the administration of, and arrangements at, the Bicêtre for the care and treatment of epileptic and defective children, and this is followed by chapters on clinical and pathological observations carried out at the institution. An excellent account is given of the classification of patients—various types of idiots, imbeciles, and "defectives"—for purposes of instruction and training. Thus at the end of 1898 there were 462 children at the institution, 45 of these being classed as non-insane epileptics. Gymnastics, fencing, dancing, &c., are taught to suitable patients, and school classes of various grades are available for teaching and manual training. During the year 74 patients were admitted, 19 died, and 54 were discharged. Among the deaths eight were attributed to epilepsy, five to enteric fever, and four to tuberculosis. At the Fondation Vallée, a tributary institution attached to the above, there were at the end of 1898 189 patients (epileptic, imbecile, and hysterical girls). The admissions amounted to 62, and there were 13 deaths, and 44 discharges and transfers. Tuberculosis seems to have been the cause of seven deaths. Dr. Bourneville emphasises the importance of the provision of special classes for feeble-minded children in connexion with the primary schools in Paris, and points to satisfactory results already achieved in England, Switzerland, and Belgium.

The clinical and pathological section teems with useful information. Chorea and its treatment by bromide of camphor form the subject of a very instructive article, and very good results are chronicled of this mode of treatment. Careful accounts of hydrocephalic idiocy and imbecility with athetosis are given. Chronic meningitis with idiocy, mania of adolescence, alcoholism and its treatment in children, febrile diseases and their treatment in idiots and imbeciles, and a valuable study of an epidemic of typhoid fever, all find appropriate mention and description.

A number of chapters of exceptional interest deal with the hereditary conditions and antecedents of patients, a subject which the French school have cultivated with especially good results. A graphic account of a case of adolescent mania with nymphomania cured after seven months' treatment and one of a boy aged 13 years, a juvenile drunkard of shockingly depraved morals, arrest attention; the latter patient having improved remarkably under treatment at the "Institut Médico pédagogique." Several excellent plates and photographs illustrate the work and add to its usefulness; they deal with such subjects as hydrocephalic and meningitic idiocy, and cerebral sclerosis, and are well executed. The volume is a worthy continuation of the series, and will be read with interest, especially by those who are concerned with the cerebral and mental affections of children, including cerebral pathology, or are attached to institutions having the care and treatment of such patients.

LIBRARY TABLE.

Dermato-histologische Technik. By Dr. MAX JOSEPH (Berlin) and Dr. GEORG LOEWENBACH (Vienna). Berlin: L. Marcus. 1900. Price 3 marks.—This is a laboratory manual of 110 pages for those who desire to study the histology of the skin and its diseases. The best idea of its scope may be gathered from the headings of its chapters: (1) Investigation of Skin in its Fresh Condition (*a*) in Sections, (*b*) not in Sections; (2) Ditto Preserved, Fixing and Hardening; (3) Embedding; (4) Cutting and Handling Sections; (5) Staining in General; (6) Special Staining; (7) Parasites; (8) Special Staining of Epidermic Structures; (9) Hairs; (10) Nails; (11) Coil and Sebaceous Glands; and (12) Special Stains for Components of Cutis. The directions are concise and the authors being well-known workers in this field their advice may be relied on, while the wealth of formulæ for the various media required makes the work a manual valuable to every student of this branch.

A Pocket Medical Dictionary. By W. A. NEWMAN DORLAND, A.M., M.D. London: The Rebman Publishing Co. Philadelphia: W. B Saunders. Pp. 518. Price 10*s*—This is a very handy and, so far as we have been able to test it, a very complete and accurate little book. It is printed on thin but opaque paper in clear type and though comprising over 500 pages is of a convenient size for the pocket. Although every practitioner should possess Dr. George Gould's incomparable dictionary it is a book which is too bulky to carry about and for this purpose Dr. Dorland's modest volume is admirably suited. There are several useful tables, such as those of the muscles, arteries, and nerves. The only point with which we are inclined to find fault is the phonetic representation of the pronunciation of French words. Thus, "abouchment," which surely should be "débouchment," is represented phonetically by "ah-boosh-maw," with an acute accent after the "w." The nasal French "n," is certainly not easy to represent phonetically, but we cannot think that the method illustrated above will aid the student.

Who's Who? for 1900. London: Adam and Charles Black. Pp. 1092. Price 3*s.* 6*d.*—This useful work has increased in size by some 80 pages since its last appearance. The general information is of great value, and in most cases, being autobiographical, can be relied upon. We expect that there are few newspaper offices unprovided with a copy of this book of reference, and its influence can be traced in one gloomy direction with great regularity—we refer to the accurate nature of the obituary notices of comparatively unimportant men in the general press. We notice that a list of the chief naval and military medical officers which appeared last year has been omitted this year, which we think is a rather untimely variation in contents.

JOURNALS.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, D. J. CUNNINGHAM, F.R.S., G. H. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G.

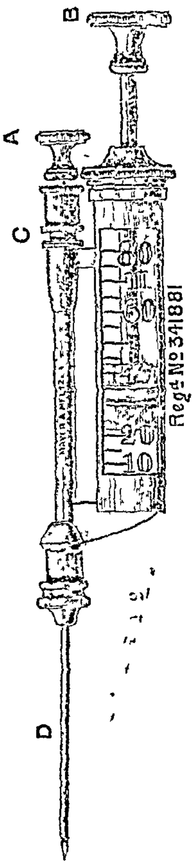
M'KENDRICK, F.R.S. Vol. xxxiv., Part II. London: Charles Griffin and Co., Limited. January, 1900. Price 6s.—The articles contained in this number of the *Journal of Anatomy and Physiology* are:—1. The Stomach and Pylorus, giving the results of an investigation undertaken with a view to determine the actual movements of the stomach during the process of distension, by Richard J. A. Berry, M.D., F.R.S. Edin., and John Crawford, M.B. Edin., with four plates. The authors show that the length of the stomach bears certain very definite relations to its transverse diameter, the exact ratio being as 1000 to 463; also that the shape of the pylorus is practically always oval, the longest axis being most frequently directed from above downwards and backwards, and that the stomach of the female is more tubular than that of the male. 2 Duplicity of the Cervix Uteri in Trichecus and Otaria, by Professor Cleland, F.R.S., with a plate. 3. On the Vitality of the Ova and Spermatozoa of Certain Animals, by James F. Gemmill, M.B. Glasg. He shows that the life of an unfertilised sea-urchin egg in sea water is comparatively short, certainly under 24 and probably under 12 hours. The eggs of the limpet may remain fertilisable up to 40 hours after extrusion. The vitality of spermatozoa of the sea-urchin may endure for 72 hours. 4. The Form of the Empty Bladder and its connexions with the Peritoneum, together with a Note on the Form of the Prostate, by A. Francis Dixon, M.B. Dub., with three plates. A valuable contribution to a field of anatomy that has been well worked over. 5. On the Structure and Functions of Hæmolymph Glands, by W. B. Drummond, M.B. Edin., with three plates, an interesting article on a subject that has received but little attention at the hands of histologists. 6. Note on the presence of Ciliated Cells in the Human Adult Kidney, by E. Wace Carlier, M.D. Edin. Ciliated cells are found living in the proximal and distal convoluted tubes and the spiral tubes. 7. A Note on the Thymus Gland in the Koala (Phascolarctos cinereus), by Johnson Symington, M.D. Edin., with two plates. 8. Symmetrical Perforations of the Parietal Bones, by A. M. Paterson, M.D. Edin., and F. T. Lovegrove, M.R.C.S. Eng., with four plates. 9 The Causes of the Entrance of Oxygen into the Blood in the Lungs, by J. J. Charles, M.D. Irel. 10. The Topography of the Facial Nerve in its Relation to Mastoid Operations, by Robert Dwyer Joyce, F.R.C.S. Irel. 11. Craniometric Observations in the Post-mortem Room, by David Waterston, M.B. Edin. 12 Ninth Report of the Committee of Collective Investigation of the Anatomical Society of Great Britain for the Year 1898–99; reported by F. G. Parsons. This report has reference to the circumflex (femoris) arteries and the perforating arteries. 13. An Australian Skull with three Supernumerary Upper Molar Teeth, by Professor Sir William Turner. 14. Archæologia Anatomica, by E. Barclay Smith, M.D. Cantab. The subject of the article is John Halle, a sixteenth-century anatomist. Lastly, the Proceedings of the Anatomical Society of Great Britain and Ireland.

Revue d'Hygiène et de Police Sanitaire. Tome xxi., No. 12, Decembre, 1899. Paris: Masson et Cie.—The interest excited during recent years in the subject of contamination of oysters and the evil results which may accrue therefrom has prompted the French Government to undertake an extensive inquiry into the topographical relation of the oyster layings on the French littoral. Dr. Mosny has been entrusted with the investigation, and the bulk of the current number of the *Revue d'Hygiène* is taken up with the first portion of Dr. Mosny's report, which is confined in the main to a historical account of the chief events connected with mussel and oyster poisoning of one or another variety. The author of the report apparently sees little difficulty in effecting the closure of certain layings, the removal to another site of others, and the suppression of the sources of pollution in others. The result of Dr. Mosny's topographical investigations, which will presumably appear in the next number of the *Revue d'Hygiène,* will be of interest to English consumers of French oysters, although in the main French oysters are introduced into this country when quite young.

The Journal of State Medicine. Vol. viii., No. 1. January, 1900. London: Baillière, Tindall, and Cox. Price 2s.—Dr. W. R. Smith's first Harben lecture on Diphtheria is published in full in this number. He treats of the history and distribution of the disease in space and time and of the conditions with which it is at times associated. He traces the varying degrees of diphtheria incidence upon the several counties and groups of counties in England and Wales during several decades, and contrasts it with the behaviour of measles and scarlet fever. The tables and maps which appeared in Dr. Smith's report to the London School Board in 1896 have been brought up to date, and additional matter with regard to the bacteriology of the disease has been introduced. Dr. William Thomson's paper on the Pollution of the Atmosphere of Large Towns which was read at the Blackpool Congress of the Royal Institute of Public Health is embodied in the volume before us, as also is Mr. Casmey's paper on the Ventilation of Industrial Buildings.

New Inventions.

AN IMPROVED EXPLORING SYRINGE.



IN designing this syringe an attempt has been made to overcome an inconvenience which is too often experienced when using the ordinary apparatus—viz., the blocking of the needle, either during its insertion or by particles in the fluid which it is intended to withdraw. It will be seen from the sketch that the construction consists of a hollow needle D, fitted with a pointed trocar which passes through an air-tight stuffing box C, and is provided with a head A. This part of the apparatus, which is similar to that supplied with some aspirators, is fixed parallel to an ordinary cylinder and piston, the needle D having a clear way through to the lower end of the cylinder. When it is required to use the syringe for exploring purposes both the trocar and the piston are pushed right in by means of the heads A and B respectively. The needle is then inserted and the trocar pulled out a few inches by means of the head A so as to leave the needle open to the cylinder. The piston can now be gradually drawn out. If when the piston is part way up the cylinder the needle should become stopped up the trocar can be pushed down to clean it. The apparatus is so designed that it can be taken to pieces for sterilising and cleaning. Messrs. Mayer and Meltzer of Great Portland-street are the makers.

CHRISTOPHER MAYHEW.

Portsmouth.

THE LANCET.

LONDON: SATURDAY, JANUARY 27, 1900.

THE second and final report of Lord LLANDAFF's Commission on the London Water Supply has just been issued The Commissioners were appointed as long ago as May, 1897, and, as our readers may remember, they held no less than 64 public sittings, at which an enormous amount of evidence was given by a large number of witnesses, full reports of which appeared at the time in our columns. The subjects on which the Commissioners were asked to report were, briefly, whether it was advisable from a financial point of view that the undertakings of the metropolitan water companies should be purchased, and if so, whether by one authority or by several authorities; secondly, if such purchase were not made, whether any additional powers of control should be vested in local or other authorities. A third point on which the Commissioners were asked to give an opinion was as to whether any system of intercommunication between the mains of the existing metropolitan water companies was practicable and advisable It will be remembered that in consequence of a failure on the part of the East London Water Company to supply their customers adequately during the summer of 1897 it became a pressing matter to see whether anything could be done to prevent such a catastrophe from happening during the next summer. The Commissioners were therefore asked to give their immediate attention to this subject, and they proceeded to receive evidence bearing on this matter from the engineers of the metropolitan water companies. No less than three schemes were submitted and the Commissioners in their first report advised that some temporary measures should be taken by which a water famine in the East end of the metropolis might probably be prevented. We dealt fully with this first report at the time of its issue and were glad to be able to record that the Government acted up to their duties and quickly passed a measure which obviated a water famine in East London. The Bill by which this work was to be made possible was opposed by the London County Council—a fact which we point out because the different actions of the London County Council in regard to the work of reforming the methods of the water-supply of London must be borne in mind by all who would understand an intricate subject

The Commissioners, having issued a report on one of the subjects of their inquiry, returned to the other issues which were presented to them They completed the reception of evidence and heard counsel's speeches and have now finally issued a report on the matters in their reference. The report is an exhaustive one The Commissioners have come to the following conclusions (1) that it is expedient that the undertakings of the metropolitan water companies should be purchased; (2) that it is advisable that the purchase should not be effected by the London County Council, but that (3) a Water Board should be established to purchase and to control the undertakings necessary for the supply of London with water; (4) that for some years the basins of the Thames and Lee will afford sufficient water for the needs of the area to be supplied; and (5) that it would cost less to put up the necessary reservoirs for the storage of Thames water than it would cost to obtain a new supply from Wales The London County Council will doubtless not agree with this report, but in the face of it it will be necessary for them to consider whether they are justified in the interests of the London ratepayers in proceeding with the Bill which they are promoting to obtain water from Wales. For many London ratepayers are doubly interested in the procedure of the Council Not only do the costs incurred by the Council with regard to their own Bills fall on the ratepayers of London as a whole, but some of the expenses incurred by the companies practically come out of the pockets of some of the London water consumers In these circumstances the London County Council should, we think, in the interests of the London ratepayers, forbear from unnecessary Parliamentary expenditure. There are many ways in which the London County Council can be useful to the water consumers of London without straining for the absolute control which the Commissioners advise Parliament not to confer upon them They have not always used the powers which are already in their possession for the protection of water consumers. We trust that they will now find time to attend to this work and we may be able to point out various directions in which their energy can be usefully expended It may be urged, from a medical point of view, that the body having charge of the public health of the metropolis ought to have charge of the water-supply. But the London County Council must justify their ability to discharge the enormous trust that would thus be confided to them.

We are by no means inclined to agree in its entirety with Lord LLANDAFF's report. We cannot refrain from noticing the fact that the Commissioners have expressed an opinion with regard to the amount of water which the basins of the Thames and Lee supply and are likely to yield. We are strongly of opinion that the Commissioners would have done a greater service to London water consumers had they collected accurate information with regard to the amount of water which the area can produce. As it is, they have relied on the authority of Lord BALFOUR's previous report—a report which it has been contended by Sir JOHN EVANS and other competent authorities has already proved fallacious.

◆

THE electorate of the University of London will do well to disregard all the partisans who try to make them believe that there is nothing worthy or distinctive in university representation, and that in the exercise of their academic franchise in the course of a few weeks they are discharging a mere humdrum political duty. The legislature of the country has given to the electorates of universities a special representation over and above that which they enjoy as citizens. The natural inference is that the privilege of selecting a university candidate or representative is special. At any rate it is additional to that enjoyed by the elector in his non-academic capacity. And the legislature has certainly meant him to bring to the task of selecting a candidate and supporting him more than the conventional set of considerations which influence the ordinary voter, as well as to encourage the choice of men as Parliamentary candidates who would not be selected by other constituencies. In saying this we in no wise disparage the ordinary constituencies and the average elector. Neither the tradition of this journal nor the spirit of the age permits us to do so. If we have representatives who do not always do what we think they should for the health and welfare of the people—which are the real end and purpose of all legislation—we have others who spare no pains towards these ends. Our legislators will compare favourably with those of other countries, and the choice of representatives by large sections of the people secures one inestimable advantage—the free discussion of all subjects both by the constituencies and by Parliament. Mistakes are made and crude and ill-formed judgments are expressed sometimes even in Acts of Parliament. But these faults are always liable to exposure and correction. All classes are made to see their fallibility and thus learn to respect the opinions of others. The more informed are the first to recognise the honesty and fairness of those from whom they differ and whose information they may know to be inferior to their own. The less informed are not slow to perceive the force of facts when made plain to them by those who know.

The Constitution that gives all classes the chance of having their views expressed in Parliament surely expects the special representation of universities to facilitate the election of men of special knowledge or authority. We believe that if the adversaries of such representation—and there are not a few—ever succeed in abolishing the university franchise it will be the fault of members of universities themselves in not protecting their privilege by selecting as representatives their most capable and distinguished men. We do not mean that the elector of a university representative is to ignore or go against his political principles in the use of his academic franchise, but we mean that he is to do his best to secure for his university an ideal representative whose qualities shall be distinctive, whose reputation shall be such as to secure deference, and whose support shall count in the House for more than his mere individual vote. We do not expect infallibility in such a member any more than in the ordinary member. Still less do we expect any assumption of airs of superiority. The ideal university member should have a record which must secure his being heard and which is likely to conciliate his hearers. His political past need not be pronounced, but there should be something in his history and in his *personnel* which would be a guarantee for liberality of sentiment in the estimation of political forces and questions. In matters of science and education it is important that he should be clear and in line with the best opinion of his time.

The University of London is about to assume the character of a teaching university and all expect for it as a teaching centre the eminence which hitherto it has well maintained as an examining body. But just at this juncture it is immensely important that no mistake should be made in the election of a representative of the University in Parliament. Somewhat undue haste has been used in putting forward candidates who, with great merits, yet do not possess the ideal qualities; but we have learned with great pleasure that Sir MICHAEL FOSTER has now allowed himself to be nominated. We have no hesitation in saying that we think his election ought to follow as a matter of course. It may not so turn out, for there are parties within this particular constituency over and above the ordinary political divisions everywhere to be found; but we are clear that Sir MICHAEL FOSTER is exactly the man who ought to sit in Parliament as a university representative. He is a candidate whose name and work and writings stand for much in the world of science and of educational literature. He speaks humorously, robustly, and well. He is secretary of the Royal Society. He is said to be Conservative, but he can have no Conservatism inconsistent with truth, which he loves, whether in politics, science, or morals.

THE discussion of medical relief for those who cannot afford to pay affords a fertile subject for controversial pens. In a country like England where so much is left to the free efforts of individuals or irregular collections of individuals, where the finger of the State is withheld, so to speak, from many a pie into which on the continent it would be pushed without dispute—in such a country it is perfectly natural that medical charity dispensed in a hundred different ways should be subjected to the free disussion of a thousand different people who for one reason or another interest themselves particularly in the matter. Such discussion is not only natural and in the circumstances unavoidable but also for the most part beneficial. It would, no doubt, be more useful still if the various critics of our system (or lack of system) of hospitals, infirmaries, and dispensaries, were to confine themselves to those particular branches of the subject with which they have had special experience. In this respect it is the lay critic who is more often at fault than the medical writer, and an article entitled "Hospital Chaos" in the current number of the *National Review* affords an illustration of this regrettable lack of discretion. The writer has collected much information upon the disposition and administration of hospitals and other places of medical charity in this and other countries and she contributes weighty arguments towards her attack upon our arrangements in England, but she seriously jeopardises the value of her opinions when she introduces discursive and fragmentary criticisms upon subjects of such purely medical and scientific interest as serum-therapy and Coley's fluid. Hers is a case of rushing in—an unguided mortal—where the angel of scientific knowledge still fears to tread save with the most wary steps. In short when Miss MORTEN descants rashly and loosely of the uses of the "stale blood of diseased horses," which possibly she imagines to be an allied product to Coley's fluid, and under the title of "professionalism" discusses with fervour and assurance the subjects of "experiment" and "empiricism," she comes near to destroying the value of the rest of her words.

Miss MORTEN is an opponent of the voluntary system of medical charity and argues in favour of the municipalisation or of the State control of hospitals. With very much of what she writes most medical men will cordially agree, and in fact similar opinions have been promulgated often enough in the columns of THE LANCET, where, as is well known, we have never advocated the establishment of State hospitals. Nobody doubts that the foundation of numerous small hospitals may lead to the deception of the public who may be induced to subscribe to undertakings apparently of public benefit which are really more in the nature of schemes for the private emolument of a few medical men. Again, Miss MORTEN puts her finger upon a weak spot when she describes the lack of coöperation existing between the various London hospitals and the difficulties besetting a patient who, finding no room in one, wishes to seek admission into another. In Paris, for instance, Miss MORTEN points out how the State control and consequent coöperation of the hospitals leads to the saving of much time, inconvenience, and even danger, ambulances having full information as to where there are empty beds. Here the writer touches upon defects existing particularly in London to which THE LANCET has already more than once given close attention. Similarly we can only acquiesce in her strictures upon the very deficient provision for hospital patients south of the Thames as compared with the comparatively excessive supply of accommodation in a small area of the west and south-west of London within which a large proportion of our general hospitals have been located

Although we agree with many of Miss MORTEN'S opinions that are derogatory to our present hospital arrangements and would support her condemnation of many small special institutions, yet we cannot accept her remedy as either desirable or as in the least likely to be brought to bear upon the management of medical charity in this country. State control—or at least municiplisation—is the reform that she suggests Now, hospitals and similar institutions exist primarily, as Miss MORTEN insists, for the welfare of their patients, and our judgment as to the success with which they are administered should be given to some extent in accordance with the satisfaction that we find among the patients. Patients may not always know what is best for their pathological conditions, but they do know when they are comfortable and well cared for. What, then, do we find if we compare hospital patients as a class in the towns of Germany and France, where there is complete State or municipal control, with members of the same class in our own towns? Is the Berlin hospital patient more ready than his London congener to enter hospital? The exact reverse is the case. Is he happier there or in receipt of greater skill or closer attention? Again the answer is, No. We have been very much deceived by our personal experiences if the hospital patient in England is not better off in all respects than the subject of medical charity in institutions where State control is paramount and where the opportunities for voluntary and individual effort are entirely obviated. The remedy for most of our hospital abuses lies not in the invocation of State or municipal aid, but in the enlightenment of public opinion and the awakening of the public conscience as to what class of person is the fit recipient of medical charity; and in the determination of the whole body of medical pr tioners to work together for the discouragement hospital abuse in all forms.

THE paper which we published in THE LANCET o Jan. 20th, "On the Results which have been Obtained by the Anti typhoid Inoculations," by Professor A. E. WRIGHT of the Army Medical School, Netley, is certain to have been read with an unusual amount of interest, more especially as this prophylactic measure is at present being submitted to most critical trial amongst our troops on active service in South Africa. We trust, by the way, that the medical officers in charge of our men will find time amongst their many other duties to make records of cases of typhoid fever occurring amongst inoculated and uninoculated men respectively, together with the mortality and severity of the cases. Such observations will be of the first value.

On Sept 19th, 1896, Professor WRIGHT, in a paper in THE LANCET dealing with the Relation of Serous Hæmorrhage to Certain Conditions of Defective Coagulability of the Blood, published his first experiments in what he termed "typhoid vaccination." On Jan. 30th, 1897, a paper appeared in the *British Medical Journal* by Professor WRIGHT and Surgeon-Major D. SEMPLE, entitled "Remarks on Vaccination against Typhoid Fever," in which it was pointed out that the object of all vaccination processes is, firstly, to achieve a degree of immunity which shall be equal to, or greater than, that which accrues to a patient who undergoes and recovers from an actual attack of the disease; and, secondly, to achieve that immunity without any risk to life or health. The first of these objects, the authors proceeded to state, can, as far as is known, only be satisfactorily accomplished by inoculating the patient with the micro-organisms (or the products of the micro-organisms) of the particular disease. The second object can be carried out in several ways. The patient may be inoculated with micro organisms which have lost their virulence for man by being passed through a whole series of appropriately chosen animals; or, as in the Pasteurian method of vaccinating against anthrax, artificially attenuated micro-organisms may be employed in the inoculations; or, lastly, the patient may be inoculated with measured quantities of dead, but still poisonous, micro-organisms. The advantages claimed for the last-named method are that there is absolutely no risk of producing the actual disease—in the case that we are considering, typhoid fever—by the inoculations; secondly, that the vaccines may be handled without incurring any risk of disseminating the germs of the disease—a matter of the greatest importance when it is considered under what conditions the inoculation of troops may have to take place; and, thirdly, that dead vaccines are probably less subject to undergo alterations in their strength than living vaccines. With reference to the second of the above objects of vaccination—namely, that there should be no risk to life or health—we *may* merely say that a considerable experience has shown that but little inconvenience results from anti-typhoid inoculation. The men inoculated suffer slight pain and tenderness on the site of inoculation and there is fever and general malaise lasting from a few hours to two or three days, rarely longer, when all of the symptoms subside.

The points which we now will consider, however, are the results which have been obtained, as shown by Professor WRIGHT'S last contribution. We fear that we cannot speak in enthusiastic terms of the statistics he has been able to quote, as a much larger number of cases will be required before any definite conclusion can be arrived at. But at the same time the results as shown in the table on page 152 of our issue last week are distinctly encouraging, quite sufficiently so to justify the medical officers in strongly advising officers and men to submit to the operation, and, as we believe has been often the case, in setting the example by themselves submitting to be vaccinated. The actual figures show that altogether 11,295 men were under observation, of whom 2835 had been inoculated and 8460 had not. The percentage of cases of typhoid fever amongst the uninoculated was 2·5, and amongst the inoculated 0·95, a difference sufficiently great to warrant further extensive trials taking place. With regard to the mortality the results are not so marked. Amongst the uninoculated the percentage of deaths was 0·34, and amongst the inoculated 0·2. We agree, therefore, with Professor WRIGHT that a certain measure of protection seems to have been conferred by the inoculation of the quantities of dead typhoid culture, and when his remarks on the conditions under which the inoculations were carried out are considered this conviction becomes intensified. For instance, Professor WRIGHT points out that the inoculated men were, taken as a whole, men who were much more liable to contract typhoid fever than the uninoculated men, for the inoculated consisted to a large, and sometimes to a preponderating, extent of young men who had only recently come out to India, while the uninoculated consisted mainly of older and more seasoned—in other words, of less susceptible—individuals. Read in the light of the above facts it is suggested that many of the results appear under a more favourable aspect than that which they present on a mere inspection of the figures given in the table. Professor WRIGHT further urges that it must be borne in mind in connexion with certain of the figures which he gives that the inoculations were sometimes undertaken in the actual presence of a typhoid fever epidemic. In conformity with this fact it was only to be expected that some of the inoculated would prove to have been incubating typhoid fever at the time of the inoculation, and in certain instances this turned out to be so. These cases are distinguished by italics in the table, and they have not been reckoned in the general summary of cases where the disease is known to have been contracted subsequently to inoculation. Professor WRIGHT points out that the results given in the table apply to men as distinguished from officers; as to the latter, no accurate statistical materials are available. It is satisfactory to learn, however, that among a number of inoculated officers who, counting only the subalterns, must now amount to several hundreds, there have been, so far as Professor WRIGHT has been able to ascertain, only five cases of enteric fever.

It is an old, but unfortunately only too true, maxim that in war many more men succumb to disease than to bullets. Typhoid fever has hitherto been the most prominent factor in increasing the death-roll of British soldiers in peace or war, and if a prophylactic measure can be found that even in some way tends to diminish the risk of infection without damaging the general health of the inoculated it should undoubtedly be employed as largely as is possible. The results so far cannot be said to be more than encouraging, hence the importance of careful observation in the present campaign is very great. Typhoid fever is so prevalent in many of our foreign possessions where large numbers of British troops have to be stationed that if the anti-typhoid inoculations should prove to be of use the discovery would be one of the most valuable to our Imperial interests that has been made during the present century. In order that the immunity conferred by the inoculation should be of full value to those seeking protection it is necessary that the effects should last for a considerable period. On this point we have as yet little information. Mr. A. G. R. FOULERTON[1] had the opportunity of examining the blood of nine people who had been vaccinated two years previously at the Kent County Asylum at Barming Heath. It was found that in four cases out of nine a definite agglutinative reaction was obtained after an interval of two years. These numbers are small, but they would tend to show that the benefits obtained are prolonged for some time. Further investigations must be made before definite results can be arrived at.

Annotations.

"Ne quid nimis."

THE WAR AND THE NATIONAL TEMPER.

WHATEVER condemnation and satire may have been heaped deservedly, and undeservedly, on our generals by foreign critics—who, as a rule, have little knowledge and no experience of South Africa, our enemy, or the circumstances with which we are dealing—these critics are, we believe, agreed that the British nation and the units who compose it have taken their reverses with fortitude and faced the changes in the situation with courage and without excitement. At the same time, they no doubt are aware—and we do not wish them to think otherwise—that the nation is feeling deeply the checks it has received, and has resolved sternly to inquire into the causes of them when the right time comes. We are, on the whole, a pleasure loving people, even if we place pleasure after business as a rule, and we have a large "leisured" class, although even these have the reputation among some of our continental neighbours of enjoying themselves sadly. At the present moment our pursuit of pleasure is for the time at an end and those who purvey pleasure for profit will during the present season suffer financially. This is not only because thousands in all classes do not know from day to day when they may hear of the death of a near and dear relative. Balls and similar entertainments are not taking place, theatres are doing badly, dressmakers are idle, and publishers are unable to sell their wares, because men and women are alike absorbed in the topic of the day; and welcome as distraction might be it could be forced upon them in an acceptable form, they have no inclination to seek it Undoubtedly the newspapers contain a great deal of matter that is widely read concerning the present campaign, but the meagre telegrams that announce the movements which are of vital importance to the nation s future welfare and the belated and curtailed letters of special correspondents, can not be held to banish the novel by simply supplying an equal quantity of reading matter to take its place If publishers are holding over books that would otherwise be in the press, and works not bearing on the topic of the day are at a discount, it must be because the attention once fixed on sterner subjects is not to be diverted to lighter ones The foreign journalist who expected to find us wailing in the streets after one of our early mishaps would not even now see any great difference in the attitude of the British public out of doors whether in the metropolis or in some country town or village He would find, however, if he had the advantage of personal acquaintance with individuals, that in all classes, but especially among those persons who have enough education to read widely and criticise intelligently, there were plain signs of the tension which has for some time existed and a considerable increase in the sternness and gravity of demeanour with which our French neighbours at all events, credit us He would also find that although the attitude of individuals towards him as a foreigner would be either polite or indifferent the English nation as a whole is very deeply resenting the attacks which foreign nations have made on us or have permitted the inferior organs in their press to make After all we reason the organs may be inferior, but they are all the more dependent on the sympathy of their readers and all the more anxious to publish what they know will increase the number of their subscribers because it expresses their views The effect of the war upon the national temper has been shown most in the desire it has aroused in all to take some part in the drama that is being enacted Among those who have tendered themselves for active service, and some of whom, we fear, have been accepted are hundreds who are probably in no way, either physically or by previous training, fitted for what they have offered to do Many of them, if it had been suggested to them that they should try six months 'roughing it on a hunting or exploring expedition at the Cape would have had no inclination to face the hardships Many would have pleaded family or business ties as altogether insurmountable objections And yet these men have voluntarily offered to endure far worse experiences than the worst they need have encountered in any private expedition for sport or pleasure, simply because the situation has evoked in them a craving to which they were strangers before It is a patriotic feeling consisting to a great extent as it seems to us in a distinctly national desire to be up and doing a genuine anxiety to take part in working out a great episode in the nation s history The craving, or whatever we may call it is to be found even in those who admit regretfully that the barriers imposed by age and incapacity are insurmountable It is the same feeling that has prompted thousands who have the poor always with them in peace as well as in war to organise work and contribute on behalf of those left behind and in need of assistance There is an element of charity in what they do but a still more powerful element is the desire to take part in what the nation is doing It is to be hoped that we are now through our misfortunes, but it is possible that we may have worse before us We trust that as a nation we shall meet either sequel with the quietness of demeanour that has won us the respect of our rivals in the world and which has nothing to do with stolidity for if we are a quiet nation and a stern one the last two months have proved that we are not a [illegible] one

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON THE OFFICIAL LECTURES AND THE MURCHISON SCHOLARSHIP

THE forthcoming official lectures will be delivered as follows the Milroy, the Goulstonian, the Lumleian and the Croonian lectures will be delivered respectively by Dr F J Waldo, Dr P Horton Smith, Dr W B Cheadle, and Dr F W Mott For the Milroy lectures Dr Waldo will take as his subject "Summer Diarrhœa with Special Reference to Causation and Prevention,' and March 8th, 13th, and 15th will be the days of delivery On the 20th, 22nd, and 27th of the same month Dr Horton Smith will deliver the Goulstonian lectures, and on March 29th and April 3rd and 5th Dr Cheadle will deliver the Lumleian lectures June 19th, 21st, 26th, and 28th are the dates fixed for the Croonian lectures which will be delivered by Dr Mott The lectures will be delivered at 5 P M We are informed by the Registrar of the Royal College of Physicians of London that the next examination for the Murchison scholarship will be held at the College on Monday, April 2nd, 1900, and two following days The scholarship is open to any student of medicine who has been a registered medical student during a period of not less than five, and not more than seven, years at a hospital in London or Edinburgh recognised by the Royal College of Physicians of London or by the medical faculty of the University of Edinburgh, and whether holding a medical qualification or not The examination will be conducted both orally and in writing and will include (1) examination of patients with reports on their cases, (2) questions on pathology and treatment, and (3) examination on specimens The scholarship is of the value of 20 guineas and is tenable for one year Intending candidates are required to send in their names to the Registrar of the Royal College of Physicians of London Pall Mall East, London, not later than March 19th with evidence of the duration of their medical studies from the deans of their respective schools

THE NEW MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD

THE appointment of Mr William Henry Power, F R S, to the important post of medical officer of the Local Government Board will, we feel sure, be hailed with satisfaction by the medical staff of the Board by the other departments, and by those many persons outside the Board who have had occasion at one or another time to seek counsel from Mr Power and to experience the mentally stimulating effect of his personal influence As a worker in epidemiology Mr Power occupies a very distinguished position his knowledge and love of natural history being associated with an insight into epidemiological problems in a way the value of which has been duly recognised by the Royal Society and which led his former chief the late Sir Richard Thorne to speak of him on more than one occasion as the prince of epidemiologists Mr Power has long since reminded the thinking world that infectious disease may not always be confined to one species, and that phenomena connected with its distribution cannot for all time be adequately or profitably explained by reference to the text books With the original attributes which Mr Power possesses we may rest assured that the work of the medical department will not stand still and that many of the epidemiological problems which are at present pressing for solution or at least for more light will be faced and taken in hand We expect too, that Mr Power will not be altogether content with the knowledge to be obtained from this country alone but that he will as necessity demands despatch one or other of his staff to different parts of the Continent, there to study the behaviour of disease and the methods adopted for its prevention or control. There is much to be done in this direction, as was shown by Sir John Simon as early as 1866 when he despatched Dr. (now Sir John) Burdon Sanderson and Dr. Whitley to study the nature and behaviour of what was locally regarded as "Siberian Plague" at St. Petersburg and in the country of the lower Vistula, and quite recently by Sir Richard Thorne. As his lieutenants Mr. Power has been given Dr. Franklin Parsons as first assistant medical officer and Dr. Bruce Low as second assistant medical officer. The work of both these gentlemen has for many years been before the profession and the public, and no doubt can be felt but that in them the newly-appointed medical officer will find able coadjutors. The investigations of Dr. Parsons in connexion with influenza, disinfection, and manure nuisances are too well known to need more than a passing notice, while his knowledge upon all matters connected with public health must have struck sanitary authorities and others who have been called upon to interview him officially as very thorough. Dr. Bruce Low has on numerous occasions in the past portrayed for us in commendable detail the behaviour of local outbreaks of disease, and the manner in which sundry so-called sanitary authorities have neglected all that part of their duties which could possibly come under the head of "sanitary"; and more recently his work on the diffusion of such diseases as cholera and plague have shown how well he is fitted for detailed epidemiological studies of this character.

THE ROD OR THE PRISON FOR JUVENILE OFFENDERS?

At the autumnal meeting of the Society for the Prevention of Cruelty to Children Mr. J. Allanson Picton suggested some noteworthy amendments to the proposed Youthful Offenders Bill. This measure, it will be remembered, has already passed the House of Lords and is to be discussed in the House of Commons during next session. It provides for the imprisonment of young persons under 14 years of age, but allows the substitution of corporal punishment at the option of the delinquent—a truly remarkable concession. A child capable of obtaining his release on these terms must surely be gifted with a moral strength which is rare indeed among juvenile offenders. Mr. Allanson Picton is of this opinion. He desires, therefore, that the corporal punishment clause should possess a more definite and reliable authority than it has at present. He would place the decision respecting its exercise where it naturally ought to be placed—in the hands of magistrates. Furthermore, he would substitute it without option for the clause relating to imprisonment. He maintains that the "ignoble smart" of a birching, which could be judiciously combined with educative detention in a truant or industrial school, is much to be preferred to the demoralising associations of prison life. He points to the fact that flagrant misbehaviour among the sons of well-to do people is scarcely ever corrected otherwise than on the lines which he advises, and the result is on the whole as satisfactory as could be expected. Another detail of his scheme requires that the age of a so-called "young person" should be raised to 17 years. Public opinion will, we hope, take careful note of these proposed amendments. We confess that they commend themselves to our judgment as eminently judicious.

ISOLATING THE PHTHISICAL INSANE.

The *Journal of Mental Science* (January, 1900) publishes a paper on the necessity of isolating the phthisical insane read at a recent meeting of the Medico-Psychological Association by Dr. Eric France of Claybury Asylum. The paper shows from the post-mortem records of the London County Asylums at Claybury, Colney Hatch, and Cane Hill that while 67 deaths were certified as due to tubercle, active tubercle was found post mortem in 112 cases, this last figure not including 10 doubtful cases. "It will thus be seen," he says, "that at these three asylums the number of patients dying with active tubercle, as compared with those certified as dying from this cause, practically stand in the proportion of two to one." A number of valuable tables of mortality follow and the conclusion urged is that cases of phthisis in asylums should be isolated in the early stage of the disease before they begin to disseminate the bacillus to the detriment of others. The tuberculin test is now generally admitted to be the most valuable diagnostic measure for indications of early mischief. Of 55 suspected cases injected with tuberculin 45 reacted and 10 did not react. Of the latter five were alive and healthy in July, 1899; the other five died and the post-mortem examinations made disclosed no trace of tubercle. In the discussion which followed the paper Sir William Broadbent, Sir James Crichton Browne, and Professor Clifford Allbutt strongly urged the needs of special provision for the isolation and open-air treatment of such cases.

THE LAW AND THE LEICESTER GUARDIANS.

The curtain has at length been rung down upon the comedy which the guardians of Leicester have been good enough to place upon the stage. The scene was the Court of Queen's Bench. In the previous acts certain of the guardians, with considerable "slimness" (to use the now so popular word), had thought to soothe the hard-hearted Local Government Board by appointing a vaccination officer who was himself opposed to vaccination. Even a Government Department, however, will turn at the last and the Local Government Board refused to recognise the appointment. The Divisional Court thereupon made a rule absolute for attachment of the recalcitrant guardians, only, not wishing to be brutal towards them, they were informed that if by a certain date a vaccination officer agreeable to the Local Government Board were appointed nothing further would happen. On Jan. 21st it was represented to Mr. Justice Channell in the Court of Queen's Bench that the 22 guardians had filed affidavits to the effect that a vaccination officer, Mr. H. E. Keyte, had been appointed, of whom the Local Government Board approved. The writs of attachment were therefore discharged and the 22 guardians were told that they would have to pay the costs. Surely a very silly comedy.

EXTENSIVE RESECTION OF THE BOWEL.

It is very remarkable how little the general working of the body is affected by the ablation of even extensive portions of its substance. One or more of the limbs may be amputated, yet the man may be none the worse, and this might be expected; but even a highly specialised organ like the kidney may be removed without harmful effect provided that its fellow is in a condition to carry on double duty. Strange is it that an unpaired organ like the spleen can be excised without, so far as we can tell, any effect on the bodily economy, and in order to explain so curious a fact we have to resort to the theory that some other part of the body has taken on the work of the portion removed. Yet more strange, however, are the cases in which important portions of the organs of digestion and absorption are excised, for these are the very foundation of all animal life. In The Lancet of Jan. 15th, 1898, we published an account of Dr. Carl Schlatter's case of complete extirpation of the stomach, the first instance of the successful performance of this operation, and later we printed a description of the physiological results of this severe procedure, in which it was shown that wonderfully little effect had been produced on the function of digestion After the event we feel able to explain such a result by saying that the digestive power of the stomach after all is not very great, and that its action is really preparatory to the action of the pancreatic secretion The stomach moreover, has but little power of absorption and therefore it is not so likely to be missed as would be a portion of the alimentary canal to which this function more especially belongs A paper which we publish in this issue goes far to answer this argument It has been specially translated for THE LANCET and gives a full account of another operation by Dr Carl Schlatter An Italian stabbed in a brawl, was found to have protrusion of more than six feet of the small intestine, and when fully examined some nine hours after the infliction of the injury the prolapsed bowel was already dying The only possible treatment was resection of the affected gut This was done and the two ends were sutured together In spite of the removal of so large a piece of intestine the man rapidly rallied and steadily improved in health and weight so that when he left the hospital he weighed 165 pounds Careful chemical estimations of his diet and of his excretions showed that the percentage of absorption of nitrogen was fully up to the normal limit but that there was a greater loss in the fat of the food than should have occurred in health His subsequent history was not quite so favourable for eight months after the operation it was found that his weight had decreased by about six and a half pounds and that he was unable to tolerate the solid food to which he had previously been accustomed He felt unequal to much work but on the whole he was in very fair condition Opinions differ widely as to the length of the normal small intestine, and there is still greater diversity as to the amount of bowel which may be removed without interference with the alimentary functions For a full account of the experiments and cases bearing on this point we must refer our readers to Dr Schlatter's important and instructive paper where they are detailed Suffice it to say that probably one third of the small intestine may be removed without any or any material interference with the processes of digestion and absorption, but that if more than this amount be taken away malnutrition, often with diarrhœa will in most cases follow As the average length of the small bowel is about 18 or 20 feet then six feet or two metres may be said to be the greatest amount of the small intestine which may be removed with impunity The nearer the ileo cæcal valve the less the effect of the removal of large portions of gut, for before the ileum is reached *most of the* important elements of the food have been absorbed The only explanation we can give of the immunity from harm shown in these extensive operations is that the human body has wonderful powers of adaptation, it can accommodate itself to its surroundings, its diet and its own conditions, but this adaptability has its limits and when those limits are passed failure in the working of the body must result

THE SANITARY INSTITUTE

THE twenty ninth course of lectures and demonstrations for sanitary officers which commences to day (Friday) at the Parkes Museum Margaret street W, will be divided into three parts Part I will comprise Elementary Physics and Chemistry in relation to Water Soil, Air and Ventilation, Elementary Statistics, Meteorology, &c., Part II will deal with Public Health Statutes By laws, Municipal Hygiene &c, and Part III will include Meat and Food Inspection The fee for the complete course is £3 3s but either course may be taken separately the fee for the first and third being £1 1s and for the second £1 11s 6d Among the lecturers are the names of Dr Edward I Willoughby, *Professor J* Lane Notter, Dr Herbert Manley Dr Louis Parkes *Dr* J I J Sykes Professor A Bostock Hill, Dr Philip Boobbyer, Dr H R Kenwood Dr Joseph Priestley, Dr J C Thresh Dr George Reid, Dr T O Dudfield, and Dr. Sydney Marsden In connexion with the lectures arrangements have been made to inspect sewage farms night shelters, and other places where practical demonstration in sanitary matters can be given, and those attending the lectures will also have an opportunity of inspecting food of various kinds unfit for human consumption

THE OFFICIAL LECTURES OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE Erasmus Wilson lectures and the Arris and Gale lectures will be delivered respectively by Mr E Treacher Collins and Mr B G A Moynihan The first named lectures, which will deal with the "Anatomy and Pathology of the Eye are announced to be delivered on Feb 12th, 14th, and 16th and the second named lectures which will deal with the "Anatomy and Pathology of some rarer forms of Hernia,' on Feb 19th, 21st, and 23rd On Feb 26th and 28th and March 2nd Dr Arthur Keith will take for his subject "The Results of an Investigation of the Anatomy of Man and High Primates to determine more accurately the Relationship of Man to Living and Extinct Forms", on March 5th 7th, and 9th Professor A W Mayo Robson will deal with "The Surgery of the Stomach', and on March 12th 14th, 16th 19th 21st and 23rd Professor C Stewart, LL D, F R S, will deliver a series of lectures on the "Protection and Nourishment of the Young in Plants and Animals The lectures will be delivered at 4 P M

DR CONAN DOYLE ON THE WAR

DR CONAN DOYLE who is about to start for South Africa as one of the staff of the Langman Hospital, was the guest of the evening at the dinner of the Authors Club on Monday night last In responding to the toast of his health Dr Doyle remarked that

> He was very optimistic about this war and the effect of it To all who had any heart in their bodies it marked a turning point in their lives as well as in the life of Great Britain Some six or eight months ago he took the chair at a peace meeting He could only say from his heart that he abjured that error He had seen more positive virtue in this country during the last three months than during the whole of the 40 years of his life He saw more alertness more self sacrifice in his own country, which had been prone to grow fat and obese and to think of nothing higher than a bank book and an arm chair Such a rousing in a nation was a grand thing and one which England peculiarly needed at this time There was not only a moral advantage in this but he saw a material one as well Why, for instance, should they punish Kruger? That man had solved a question which every statesman had found insoluble He would build a monument to Kruger the size of St Paul's—putting him under it—and he would inscribe across it "*To the* memory of the man who federated the British Empire' Kruger was the man in all the world who had made the British Columbian feel that he was blood brother with the Queenslander

ENDEMIC HÆMATURIA

IT is now universally acknowledged that the endemic hæmaturia of South Africa is due to the presence in the blood vessels of the bilharzia hæmatobia, but there is still much diversity of opinion as to the route by which this parasite gains entrance According to one theory the organism is taken in with the drinking water, perhaps freely swimming, or more probably as a parasite in some intermediate host In favour of this theory is the fact that in no small proportion of the cases the adult bilharzia has been found in the portal vein and its tributaries, pointing to the idea that it has entered by the alimentary canal There is, however, another theory which claims that the parasite enters the meatus urinarius during bathing or gets under the prepuce and subsequently passes into the urethra. The fact that males are much more frequently attacked than females, that the veins of the urinary apparatus, especially of the bladder, are the seat of the organism, and, further, that the Kaffirs of Natal are said to tie a string round the penis while bathing, are decidedly in favour of this mode of ingress. The Kaffirs claim that in this way they are able to prevent the disease. It is by no means improbable that the parasite may enter the body by both of these methods, though hæmaturia would probably only follow the invasion by the urinary route. In any case it would be well for our army medical officers in South Africa to bear in mind this danger to our troops.

THE QUESTION OF INDECENT LITERATURE.

MR. HAVELOCK ELLIS writes to us upon this difficult subject. After referring to the recent destruction by order of a bench of magistrates of a number of copies of "Studies in the Psychology of Sex" he continues—

> "I should like to be allowed to state that, so far as I am concerned, I can have no quarrel with the police on this matter. After the unsatisfactory conclusion of the Bedborough prosecution I resolved not to issue my work in this country, and I have strictly adhered to that resolution. The University Press, Limited, so far as they had the handling of my work, were under engagement to issue it only from Germany and not to advertise it without consulting me. They have, however, evaded the spirit if not the letter of their agreement by stocking a certain number of copies in England, and they have issued a circular which, though, as I understood, it was only sent out to the profession, I emphatically disapproved of. I addressed repeated protests to the publishers, and I cannot complain if the police have now enforced my protests. I am content to issue my work in America, where a medical publisher is unhampered in distributing a medical work to the profession. The wider question, unfortunately, still remains where the Bedborough prosecution left it. A work which (both before and since that prosecution) has met with the approval—without a single dissentient voice, so far as I am aware—of competent authorities and medical organs, not in this country only but throughout Europe and America, cannot here be sold even to members of the medical profession. It is perhaps significant of the feeble influence which medical opinion possesses in this country. In any case, however, I have no intention of fighting for that recognition which the law, as embodied in the police, refuses to grant. I must be content to devote my energies to doing my own work and leave the next step to others."

In our issue of Nov. 19th, 1898 (p. 1344) we commented in a leading article upon the results of the Bedborough trial and pointed out that the moral for scientific authors was obvious—namely, be careful about the publisher. Mr. Havelock Ellis appears to feel that he has neglected exactly this precaution. We have every sympathy with him in the position in which he was placed by the Bedborough trial.

DUTIES OF SCOTCH MEDICAL OFFICERS OF HEALTH AND SANITARY INSPECTORS.

THE Local Government Board for Scotland has by means of an order dated Jan. 18th, 1900, recalled the regulations as to the duties of medical officers of health and sanitary inspectors which were issued by the Board of Supervision in 1890. They have in place thereof, and largely by virtue of the fact that certain local authorities have failed to themselves make the regulations incumbent upon them by the statutes, issued draft regulations which may be adopted by the local authorities and which relate to the duties of both medical officers of health and sanitary inspectors. The Local Government Board has in addition called upon each of these officers to make a report to the Board for the year ending Dec. 31st upon the sanitary *conditions of his district* during 1899. The report of the medical officer of health is to contain a detailed account of what has been done during the year, very much in the same manner as is required of medical officers of health south of the Tweed, while the sanitary inspector, amongst other things, is to forward a general account of the sanitary state of the district as regards water-supply, drainage, scavenging, nuisances, &c. This duty of reporting upon the water-supply of the district—that is if the instruction implies an account of the source, storage, and filtration of the water-supply—seems to us a little outside of the province of the inspector and rather calculated to give rise to some misunderstanding between this official and the medical officer of health. With regard, however, to the relation of these two officials to one another we are glad to see that in the regulations relative to the duties of each the local authority, if they wish the medical officer of health to superintend the work of the sanitary inspector, are to introduce a special clause for the purpose; although, be it noted, the draft regulations are not without unmistakeable indications that such control is in large part contemplated by the Board, at any rate in so far as the management of infectious disease is concerned. In the regulations as to the duties of both of the officers here referred to, the instructions are in certain instances less general and more specific than is the case with those in force for English officials. For instance, the sanitary inspector is instructed to visit the common lodging-houses and the houses let in lodgings at least once every calendar month. There is much to be said for these precise instructions and later they may perhaps be introduced into the English regulations.

"A LIVING CENTAUR."

UNDER this fantastic title a curious example of genu recurvatum congenitale is on exhibition at the present time at the Royal Aquarium. The freak in question is a negro, 23 years of age, who gives an exhibition of his equine attainments by running, trotting, and pacing on all fours. He is able to assume this position with considerable ease owing to the condition of his knee-joints. These are over-extended to such a degree that the legs form a very obtuse angle with the thighs, while the backward projection of the condyle of the femur gives the joints a superficial resemblance to the hock of a horse. The amount of movement possible in the joints is extremely limited, there being practically no power of flexion. When sitting with the body vertical and the thighs in contact with the ground the feet are elevated to a height of about six inches from the floor. According to the showman the patellæ are entirely absent. After such a superficial examination as was possible in a showroom the left patella appeared to us to be present although atrophied, while the right could not be certainly felt. Mr. Shattock[1] has pointed out that the patellæ are often thought to be absent in these cases owing to the fact that they lie in contact with the concave anterior surface of the femur just above the trochlear surface and are therefore difficult to detect. The movements of the lower limb in running upon all fours take place mainly at the hip-joints, the feet being brought forwards by a movement of circumduction. The hip-joints are capable of flexion to a sufficient extent to allow of the anterior surface of the thighs being brought in contact with the trunk and the feet being placed over the shoulders, so that the man is able to scratch the back of his head with his toes. When running on all fours and viewed from the side the gait bears a curious resemblance to that of a trotting horse, although when seen from behind the movement of circumduction at the hips is very evident. The influence of a maternal impression is, of course, forthcoming as an explanation of the condition, the story being that his mother was bitten in the left arm by a vicious horse when five months pregnant. Further colour is given to this tale by the condition of the man's left arm This is kept extended and somewhat rotated in, and there is complete loss of movement at the elbow joint although no definite signs of disease of the joint are present. The biceps muscle is somewhat atrophied, probably as the result of the absence of movement, and this fact is made use of by the showman as a ground for his assertion that the muscle is placed upon the wrong aspect of the limb. The claim of the "living centaur" to be a descendant of Ixion and Nephele will, we fear, not stand investigation, but he is at any rate an interesting and marked example of a somewhat uncommon congenital deformity.

GALL-STONE CREPITUS AND FRICTION IN DIAGNOSIS.

IN the *International Medical Magazine* (New York) for December, 1899, Dr J. M. Anders calls attention to the value of gall stone crepitus and friction in diagnosis—signs which appear to have received very little notice and which are not looked for as much as they should be. Dr. E. M. Brockbank, in speaking of latent calculi, refers to cases in which they were felt like nuts in a bag Frequent and patient practice has taught Dr. Anders that when calculi can be felt crepitus is rarely absent. The following case illustrates the value of gall-stone crepitus in diagnosis A woman, aged 52 years, was seized with severe pains in the right hypochondrium which at times extended to the right shoulder and the back, and were accompanied by nausea. The attack lasted a day and then disappeared, but returned in a couple of days There was no jaundice but the stools were somewhat deficient in bile. The liver was slightly enlarged and the gall-bladder was slightly distended. Analysis of the urine showed that bile was absent. While a suspicion of cholelithiasis was aroused the absence of jaundice and chills or febrile disturbance threw doubt on the diagnosis. The patient was then examined carefully for calculi in the gall-bladder Deep palpation, combined with a gentle lateral up-and-down movement of the finger-tips, elicited a distinct, fine, grating sensation (crepitus). On operation 150 calculi were found in the gall bladder. In a second case there were symptoms of indigestion for two years with from time to time pain in the lower epigastric region and only occasionally in the hypochondrium. The epigastrium and region of the gall-bladder were very tender. The gall bladder was somewhat distended and the liver was slightly enlarged. On deep palpation during inspiration crepitus was felt. In a third case the patient was a woman, aged 60 years, who came under treatment in November 1897. What appeared to be attacks of indigestion began in August, 1896, and recurred at intervals of several days. After two months jaundice supervened. Slight pain was constant and paroxysms of colicky pains were experienced at times. They were not severe and according to the patient were not accompanied by deepening of the icteroid tint. Examination showed enlargement of the liver and a dense mass of the size of a hen's egg in the region of the gall bladder. Carcinoma of the liver or its appendages had been diagnosed by several physicians but the duration of the jaundice for more than a year and the absence of cachexia were opposed to this view. Palpation gave a negative result, the patient being rather stout, but on combining auscultation with palpation a faint grating sound was heard Treatment by olive oil was followed by the passage of large numbers of calculi. In obese subjects (in whom calculi are common) crepitus cannot be felt on palpation. The writer suggests that the combined method of palpation and auscultation should be used when crepitus cannot be elicited by palpation or friction heard on auscultation. In examining for crepitus the patient should be in the dorsal decubitus position with the legs flexed. The area of the gall-bladder is then deeply palpated. If crepitus is not obtained the finger-tips should be dipped into the abdominal wall just below the fundus of the gall-bladder and then drawn upward over the organ as though attempting to roll the fundus forward and upward. If this fails the patient should inspire deeply but slowly, during which gentle counter-pressure should be made with the finger-tips. The tactile sense may be increased by pressing on the fingers with the disengaged hand so as to put the muscles of the examining hand at rest. When palpation fails auscultation should be practised

PRIVATE LABORATORY LEGISLATION.

THOSE who carry on the work of scientific research in private laboratories may well be dismayed at the prospect of State interference, yet it has been proposed in Germany to introduce a Bill which will provide some sort of public control. According to our Berlin correspondent it is said that the Bill will contain provisions by which investigators will be compelled to take precautions against the escape of pathogenic germs. There is little doubt that the contemplation of such a measure has been inspired by the unfortunate outbreak of plague which occurred in a hospital in Vienna and which was traced to the escape of infective material from a bacteriological laboratory. We agree that excessive care must be exercised by all bacteriological investigators when they are dealing with the cultivation of highly pathogenic organisms. In most of the capitals of Europe there are many laboratories of the kind which are, so to speak, nurseries of the seeds of disease, and it is right that some effectual barrier should be placed round these centres of just possible infection. Nevertheless, it would be a sad thing for the future of bacteriological research if it can only be carried out in State laboratories. We do not hesitate to say that the brilliant results of bacteriological researches, and chemical and physical researches too, during the past decade have had their origin in private laboratories. It will be interesting to learn the exact terms of the proposed Bill. It is to be hoped that it will not interfere with clinical practice in its relation, for instance, to the examination of sputa and other pathological products. The bacteriological investigator knows well the danger of careless practice in his researches with pathogenic organisms. The outbreak of plague was of a very exceptional kind, and the fact that there are scores of laboratories in this and other countries in which diligent work has been prosecuted without the slightest hitch is a forcible argument that State interference is not needed. Indeed, we venture to say that it would hardly be brooked in this country, but would be held as unduly meddling with the liberties of the individual and as constituting a distinct obstacle to the advance of scientific knowledge.

PLASTIC ACTIVITY OF THE ANIMAL CELL.

M. L. RANVIER under this title gives in the January number of the *Comptes Rendus* for the present year the details of a curious observation which he has recently had the opportunity of making. He states that having gradually heated to 36° C. the peritoneal serum of a rat which contained some air-bubbles he noticed that the lymphocytes of the fluid moved towards the bullæ and on arriving at their surface became flattened just as the cells would have done if they had impinged against a solid substance. If the temperature was allowed to fall to 21° C. the cells again assumed the spheroidal form. On increasing the temperature they once more became flattened. M. Ranvier suggests the term "plastic activity" to denote this phenomenon, for he regards the change of form as the consequence of the activity of the cell or, in other words, considers it to be a vital phenomenon. He was, he believes, the first to notice the flattening of lymphocytes against solid bodies, but acknowledges that he should not have expected such flattening to take place against an air-bubble. It seems to show, he thinks, that cells are highly sensitive and possess extremely delicate motor reactions. The best mode of performing the experiment is to dust a little starch on a slide, then to permit a drop or two of the peritoneal fluid to fall amongst the grains, and gently to lower the cover which thus comes to be supported by the larger grains of starch. A few bubbles of air are then introduced into the fluid. The heat may be applied by approximating a fifty-candle power electric light or by using the ordinary warm-stage.

OPENING OF THE NEW BATHS AT HELOUAN.

The little town of Helouan, situated in the desert about 15 miles south of Cairo and three miles from the Nile, has been for many years a resort of invalids, especially rheumatic invalids, on account of the natural waters which are abundant there. Some years ago the place became fashionable on account of the fact that the Khedive Tewfik found much benefit from the waters, but after his death Helouan to some extent suffered an eclipse. Lately, however, its virtues would appear to have been re-discovered, for an installation of baths and bathing appliances, embodying all the most recent forms of apparatus in use, has taken place. The new bathing establishment has been formally opened by his Highness the Khedive.

THYROID EXTRACT IN THE TREATMENT OF TUBERCULOSIS.

Professor Edwin Klebs reports in the *Berliner Klinische Wochenschrift* (Dec. 11th, 1899) the results of trials and studies made by him on the above subject, as he announced at the meeting of the Tuberculosis Commission at Munich. He used the juice of the thyroid as obtained by pressure and administered it to the subjects of phthisis in an early stage, all of whom were markedly suffering from gastric symptoms (achylia gastrica), while the changes in the lungs were but slight. The drug was not given empirically or in haphazard manner, but in accordance with the results of experiments carefully carried out previously on animals, in which Klebs had found that when the thyroid gland had been removed the same gastric conditions resulted as was the case in the patients alluded to above. It must also be noted that these patients were found to present a noticeable atrophy of the thyroid gland. The gastric juice in dogs experimented on after ablation of half of the thyroid gland and simultaneously subjected to injections of tuberculin was found to be almost entirely devoid of hydrochloric acid and of pepsin, while the intact half of the dog's thyroid was found to be undergoing atrophy with a total disappearance of its colloid substance. It thus appeared as though the action of tuberculin was inimical to the thyroid function and that as a net result there supervened after awhile the gastric conditions referred to above. Concluding from these experiments that the feeding of tuberculous patients who suffered from severe achylia gastrica with fresh thyroid secretion might have a beneficial effect, the theory was carried out into practice with the result that much benefit was obtained by this method of treatment. Klebs records the clinical history of two phthisical patients thus treated and points out that in both cases a marked improvement of bodily condition and an increase of weight followed the treatment. Other improvements in respiratory capacity and in respiration generally are also recorded and a marked increase in appetite which before had been very feeble.

A NEW FONT FOR HOLY WATER.

We have received from Mr. J. J. Bruns, jun., of Arnhem in Holland, several pamphlets on the possible danger of various infections being communicated through the medium of the holy water contained in the ordinary font in the vestibule of a Roman Catholic church. Mr. Bruns had his attention first directed to this subject by the serious illness of his son, a boy seven years of age. One day in 1892 the father and son went to one of the churches in Arnhem and soon after their entry the boy complained of his left eye, saying that something had got into it from the holy water. Medical advice was at once obtained and in two days the boy was taken to Utrecht to Professor Snellen, under whose care he remained for three months. The state of the eye was very serious but eventually it was saved. Mr. Bruns at first doubted whether the holy water had really been the cause of this misfortune, and to throw some light on the question he had a great many samples from churches in different towns in Holland submitted to microscopical examination. The result was the discovery in most cases of abundant bacterial growth with occasional presence of staphylococci and other pathogenic forms. Two guinea-pigs injected intra-peritoneally with sediment from the holy water of a church in Amsterdam died in 30 hours from peritonitis, and two others injected subcutaneously with the same suffered from purulent inflammation at the place of insertion. In November, 1896, Mr. Bruns devised a means of completely avoiding this contamination. The holy water is stored in a narrow-necked jar inverted in a shallow basin so that the outflow from the jar ceases as soon as the water in the basin covers the neck of the jar. One end of a bent tube filled with hair is immersed in the water in the basin and the other end, overhanging the edge, delivers a constant stream of small drops raised by the capillarity of the hair. All these parts are enclosed in an ornamental oaken case somewhat resembling that of a timepiece. This case projects from the wall, and the stream of drops falls through an opening in the bottom of the case into a receptacle which at once carries away the excess, and the congregation on entering the church have merely to hold their fingers for an instant in the stream. The apparatus was submitted to Monseigneur van de Wetering, Archbishop of Utrecht, who expressed his approval of it, and by his secretary wrote to Mr. Bruns authorising the mention of his name in connexion with it.

PUBLIC VACCINATORS AND REVACCINATION.

It appears from a Hull newspaper that the Patrington Board of Guardians are in some mental confusion as to their duty with regard to the payment to their public vaccinators of fees for revaccinations. One member "contended that revaccination fees were not legal and would not be passed by the auditor," and he referred to the inspector as having held that such fees should only be paid under protest. After discussion it was decided not to pay the bills in the meantime. The attitude of the guardians is difficult to understand in presence of the plain provisions of the Vaccination Acts, of the Local Government Board order, and of the contract entered into by the Patrington Board of Guardians and quoted at their meeting. Section 8 of the Vaccination Act of 1867 gave power to the Privy Council to issue regulations as to the revaccination of persons applying to be revaccinated. A later Act transferred these powers to the Local Government Board. Article 3 of the Vaccination Order of 1898 deals quite clearly and specifically with revaccination, fixing the minimum fee for every successful revaccination at 5s or 2s 6d, according as the operation is performed at the home of the vaccinee or elsewhere The only reservation is that no payment shall be made where the person revaccinated is under 10 years old, or has been revaccinated within 10 years Subject to this proviso and to their own contract made in terms of the Board s order, the guardians have no choice but to pay, unless indeed they propose to repudiate their debts and to trust that fear of dismissal may prevent their officers from taking legal proceedings to enforce payment Of course, all this has nothing to do with compulsory revaccination Most unfortunately for the public safety and by no means to the credit of the present Government there is no pressure or compulsion in the matter; but even under the existing law anyone who chooses has a right to demand revaccination at the hands of the public vaccinator, and that official has a right to insist on the guardians paying him for such revaccination

THE RECENT EPIDEMIC OF PLAGUE IN PORTUGUESE INDIA

FROM the report on the plague in Daman by Dr Viriato João Pinto, the special commissioner of the sanitary authority of Portuguese India, which has recently reached us, we learn that during the continuance of the epidemic from September, 1898 to October, 1899, 504 persons were attacked, of whom 303 died—a mortality of 60 1 per cent A copy of the correspondence which passed between the Portuguese and the British sanitary authorities is appended, as also are a number of statistical tables and charts

THE arbitrators, Sir James N Dick, K.C B, Colonel C Bowdler, and Inspector General Belgrave Ninnis, M D, R N, who were appointed to decide upon the difficulties which had arisen at Stockport with regard to the local branch of the St John Ambulance Association have delivered their opinion They find that the Stockport Centre has not discharged its duties in a satisfactory manner, but no blame attaches to the chairman, that the chairman of the centre should summon a meeting of those gentlemen whose names are on the list as members of the committee and consult with them as to the best method of reviving the committee, and that Mr Ferns should be re appointed secretary provided that he can satisfy the committee as to satisfactory relations being preserved with the medical profession in Stockport

WE learn that a draft memorial is to be presented to the Local Government Board by the Central Hospital Council for London with a view of obtaining for hospitals exemption from local rates This has been submitted to the Council of the Metropolitan Hospital Sunday Fund for their support The Council of the Metropolitan Hospital Sunday Fund, while giving their general assent to the principle advocated in the memorial, have asked their General Purposes Committee to consider and report upon it

THE annual general meeting of the Neurological Society of London will be held on Thursday, Feb 8th, 1900, at 8 30 P M, at the rooms of the Medical Society of London, 11 Chandos street, Cavendish square, W, when the President-Elect, Dr A D Waller, F R.S, will deliver an address on the Excitability of Nervous Matter with Special Reference to the Retina

DR. BURNEY YEO has been appointed by the Council of King s College, on his resignation of the chair of Medicine, Professor Emeritus and Consulting Physician to King s College Hospital

THE annual discussion of the West London Medico Chirurgical Society will take place on Friday, Feb 2nd, commencing at 8 30 P M The subject, The Treatment of Primary and Secondary Syphilis,' will be opened by Mr Alfred Cooper, and visitors are invited to be present to take part in the discussion

SIR HUGH REEVE BEEVOR, Bart, M.D, F.R C P Lond, has been elected the representative of the Society of Apothecaries on the General Medical Council for one year from Feb 6th

THE man Hopwood, to whose committal we referred in our issue of Jan 20th (p 182) has been sentenced at the Birmingham Quarter Sessions to 15 months' hard labour

THE treasurer of the Metropolitan Hospital Sunday Fund has received the sum of £1090 3s 3d from a bequest of the late Mr Thomas King of Tisbury

THE ROYAL COMMISSION ON THE METROPOLITAN WATER SUPPLY.

THE Royal Commissioners who were appointed to inquire into the subject of the water supply within the limits of the metropolitan water companies have just issued their final report The Commissioners, it may be remembered, were appointed on May 1st, 1897, and the Commission originally consisted of Lord Llandaff, the Right Hon John William Mellor, Sir John Dorington, Sir George Barclay Bruce, Mr Cripps, Q C, Mr A de Bock Porter, and Major General A de Courcy Scott, the water examiner appointed by the Local Government Board The secretary was Mr Cecil Owen The terms of the Commission embraced three chief issues (1) whether having regard to financial considerations the present metropolitan water companies should be purchased and in case of purchase whether they should be acquired and managed by one authority or by several authorities, (2) whether if the under takings were not purchased it was advisable that additional powers of control should be exercised over them, and (3) whether it was practicable to connect two or more different systems of supply in the administration of the metropolitan water companies and if so by whom and in what proportion the cost of connecting them should be borne and what legal powers would be necessary to give effect to any such arrangement

In consequence of the failure of the water supply in the East of London and a fear that such a misfortune might again take place the Commissioners were requested to obtain evidence and report as quickly as possible on the third issue which was presented to them The Government realised that a water famine in the East end might cause great distress to the inhabitants and it was hoped that if some practical scheme could be immediately devised and carried out this deplorable state of things might be obviated, at any rate for a time Evidence was therefore taken by the Commissioners, three schemes were submitted to them and as a result of their inquiry they issued their first report of which a full digest was given in THE LANCET[1] As the result of this report the Government introduced a Bill which made it legal that inter communication between the mains of the various companies should be at once carried out under the supervision of the Local Government Board and inter sale of water between the different companies was permitted As the result of this Bill a considerable quantity of water was supplied to the East London Waterworks Company and the East end of London was fairly well supplied with water during last summer

The first report was signed by all the Commissioners Since that time two of their number have died—Mr Cripps Q C, and Major General Scott. The second and final report is therefore signed only by the six surviving Commissioners

---

[1] THE LANCET Jan 28th (p 241) Feb 4th (p [illegible]) and Feb 11th (p 383 1899

The intimate knowledge possessed by Major-General Scott of the whole of the works of the companies which supply London with water, his knowledge of engineering, and his thorough acquaintance with the whole of the details of this complicated subject must have made his advice to the other Commissioners of the greatest possible value. It was evident in many of the 64 public meetings which were held that Major-General Scott was able to direct the evidence to points of the greatest importance which might otherwise have escaped notice, and that his help, always given quietly and unostentatiously, was appreciated by some at least of those Commissioners who were naturally not so fully informed as he was as to the nature of the technical evidence which was given. The Commissioners state in their report that they met on 84 days and there were therefore many private sittings on which Major-General Scott's knowledge must have been of service to the Commissioners, and when he had naturally an opportunity of speaking with greater freedom than was possible at a public meeting. It is a pleasure to point out that the Commissioners have recorded their sense of obligation to Major-General Scott, who they say was able to supply them in October last with a full statement of his opinions on the subjects of their inquiry, and they add that they have largely availed themselves of the valuable assistance he thus afforded in framing their report.

We have mentioned that on one issue the Commissioners' report has already been given, and the practical results which have been gained. It remained for the Commissioners to report on the two first issues which were submitted to them, and it may be well to give exactly the terms of reference. The Commissioners were instructed to inquire and report:—

> 1. Whether having regard to financial considerations and to present and prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies, it is desirable in the interests of the ratepayers and water consumers in those districts that the undertakings of the water companies should be acquired and managed either (*a*) by one authority, or (*b*) by several authorities; and, if so, what should be such authority or authorities
>
> To what extent physical severance of the works and other property and sources of supply of the several companies and the division thereof etween different local authorities within the limits of supply, are cticable and desirable; and what are the legal powers necessary to effect to any such arrangements
>
> If the undertakings are not so acquired, whether additional powers ontrol should be exercised by local or other authorities; and, if so, hat those powers should be.

At their first meeting which was held on May 29th, 1897, the Commissioners decided that their sittings for the reception of evidence should be open to the public and to representatives of the press, and that the parties concerned in the inquiry should not be represented by counsel. Pressing applications were, however, received from the metropolitan water companies and from the London County Council to reverse their ruling in that respect, and having regard to the vast pecuniary interests involved the Commissioners decided to allow counsel to appear on the understanding that they should only examine witnesses or address the Commissioners on points which were in the opinion of the Commissioners desirable. The metropolitan water companies, the London County Council, the Corporation of London, the county councils of Middlesex, Surrey, Kent, Essex, and Hertfordshire were then invited to give evidence. Of these bodies the London County Council tendered the evidence of many witnesses and occupied no less than 17 days of their sittings. Amongst other witnesses were Sir Alexander Binnie, their chief engineer; Mr. H. E. Haward, their comptroller; Mr. G. L. Gomme, their statistical officer; Mr. H. L. Cripps, their Parliamentary agent; Mr. Shirley Murphy, their medical officer of health; and Mr. W. H. Dickinson, the chairman of the Water Committee. Three other members of the council gave evidence—Sir John Lubbock, Sir Arthur Arnold, and Mr. C. A. Whitmore. The Corporation of London appeared through their Remembrancer, Mr. Gabriel P Goldney. The vestries and district boards of works within the county of London were invited to tender evidence either by sending witnesses or by giving their opinions in writing, and of 42 authorities 28 replied. Evidence was also given on behalf of the county councils of Middlesex, Surrey, Essex, Hertfordshire, of the county borough of Croydon, the borough of Richmond, and the Croydon District Council.

The Commissioners state that the information which they desired to obtain from the water companies was very readily given, and they examined at length Mr. Middleton (one of the engineers of the Staines reservoir scheme), Mr Hunter Sir Frederick Bramwell, Mr. Charles Hawksley, and Mr. E. W. Eaton. Sir William Crookes and Professor Dewar gave evidence as to the quality of the water supplied. The late Sir Edward Frankland (the official analyst), Mr. Allen Stoneham (the auditor appointed by the Local Government Board to examine the accounts of the water companies), the chairman and engineer of the Thames Conservancy, and the clerk of the Lee Conservancy Board were also examined. Reports of the evidence given by these witnesses have already appeared in THE LANCET, and it will doubtless be shortly published *in extenso* from the shorthand notes taken for the Royal Commissioners.

At the commencement of their report the Commissioners point out that there were some considerations of great weight on the question of the advisability of purchase of the London water undertakings which seem to them to be excluded from their inquiry. For example, the Duke of Richmond's Commission in 1869 gave it as their opinion that the control of the water companies of London should not be in the hands of trading companies, but that on grounds of public policy the water companies should be under public control and entrusted to a responsible body. With regard to the question of public policy the Commissioners come to the conclusion that they were not asked to pronounce an opinion. In the course of their inquiries it was, they point out, contended, on the one hand, that various legal enactments which had been already made, as, for example, the sinking fund clauses which regulate the raising of new capital by the metropolitan water companies, expressly contemplated the ultimate purchase of the companies' undertakings. It was urged, moreover, that the connexion between public health and the water-supply strengthened the feeling in favour of its municipalisation. On the other hand, it was contended that it was inexpedient from a financial point of view that any representative body largely elected by the working classes should by the purchase of such an undertaking as the supply of water become a large employer of labour. The Commissioners decided that the real question which they had to determine was the expediency of purchase in the interests of the ratepayers and water-consumers on financial grounds alone and with regard to the future as well as the present requirements of Water London. This, however, they insist is one only of the considerations which have to be taken into account before a policy of purchase is adopted or rejected, but it appeared to them to be the only question which they were instructed to advise upon. Early in the course of their inquiry the Commissioners found it necessary to consider whether or not it was their duty to re-open questions which had been reported upon by the Commission presided over by Lord Balfour. They came to the conclusion that they were not empowered to reconsider the matters which had been so recently decided, and at their second public meeting, which was held on Dec. 6th, 1897, they gave a public intimation to the effect that the questions on which Lord Balfour had reported would not be re-considered, and that speaking generally they accepted the findings given in the Balfour Report.[1] In consequence of this decision much evidence which the county council of Hertfordshire and the London County Council wished to bring before the Commissioners was necessarily excluded. This evidence dealt with the actual amount of water which can be obtained from the present sources of supply. The London County Council then contended that on financial grounds alone it would be better for the people of London to obtain as quickly as possible a new supply of water from Wales. The Commissioners therefore felt bound to consider evidence tendered on this subject and they found it "voluminous and conflicting" The estimates given were of so technical a character that it became necessary to appoint an assistant commissioner, Colonel W H Rathbone, whose services they found of great value in assisting and helping them to form some opinion as to the comparative cost of bringing a new supply of water from Wales and of making additional storage reservoirs in the valley of the Thames so that more water could be obtained from that source.

The Commissioners considered in detail the financial position of the metropolitan water companies and the terms of arbitration on which the water companies should be bought; they give a digest of the contentions of the London County

---

[1] Report of the Royal Commission appointed to inquire into the Water supply of the Metropolis, 1893.

Council on this matter and then go on to inquire what the financial results of such an arbitration would be likely to be. The opinions of local authorities with regard to the expediency of purchase are summarised and an account is given of cases in which water supplies have been purchased by provincial corporations. The Commissioners then give their views of the present and prospective requirements of Water London and their opinion as to the expediency of purchase. Stated generally, say the Commissioners, the requirements of the population are: a supply of pure and wholesome water constantly laid on at such a pressure as to make the water reach the top storey of the highest house and in quantity sufficient from time to time to meet the needs of the growing number of inhabitants. In order to obtain such a supply it is not necessary at present to go far afield for the water, but they think that, having regard to the prospective requirements of supply in Water London, it is desirable that the undertakings of the water companies should be acquired and managed by a public authority. They then pass on to consider by what authority the purchase should be effected. On this point they insist on the fact that only one public body has manifested a desire to buy the undertakings of the metropolitan water companies and that it is admitted that if such a purchase were made the undertakings would have to be divided in such a way as to give the outlying authorities their share of them. This severance would be a costly proceeding. Inasmuch, then, as all the metropolitan counties except Hertfordshire are bent on demanding what the London County Council are pledged to concede—that is to say, their own share of the undertakings—they think that a purchase by the London County Council must necessarily be followed by a severance and division of the works of supply, and this course appears open to so much objection that it is practically inadmissible. The supplies of water which can be obtained from basins of the Thames and Lee are, the Commissioners believe, sufficient to supply London for many years to come, and should efficient conservancy of the rivers be maintained and the river water be adequately treated, the wholesomeness of the supply can, they believe, be maintained. The undertakings should in the public interest be placed under the control of a permanent Water Body and not of a fluctuating body. They suggest that a Water Board should consist of not more than 30 members, that these should be selected on account of their business capacity and knowledge of matters connected with water-supply, and that the Board should be so constituted as not to give a preponderance to any one of the conflicting interests concerned. The size and importance of the area affected make the matter one as much of national as of local concern and for that reason the Commissioners think that the proceedings of the Board should be brought automatically and periodically under the observation of Parliament, and that it should include delegates of the Local Government Board in order to ensure that the influence of the Executive Government should be continuously felt The Commissioners then go on to suggest what the composition of the Water Board should be and what powers it should have. The latter part of the report is occupied by the question of the powers of control which might be exercised over the existing water undertakings and this important subject is considered in some detail. The report has evidently been drawn up with very great care and it deserves study. We have been able here only to describe its more salient features, and in concluding this brief notice we may mention the fact that the report is provided with a careful index consisting of no less than 10 folio pages. The Balfour report issued on its first publication contained no such index and we must highly commend this innovation, which is doubtless due to Mr Cecil Owen, who, we are glad to see, receives in the last paragraph of the report an appreciative note on the excellence of his services.

VITAL STATISTICS OF THE DUTCH NAVY IN 1897.

AT the present moment the vital statistics of the naval and military forces of any European nation are important to us, for when the Boer war is over there is no doubt that considerable reorganisation of our defences will take place, when all reliable hygienic information will be welcomed. The admissions to hospital per 1000 of strength in the Dutch Marine Service during the year 1897 were as follows: Europeans, 1975; Asiatics, 1325; Africans, 1461; the average strength in the three categories having been 17,254, 32 833, and 80 respectively. By far the larger proportion of the disability was due to what are collectively termed "palustral fevers," the admissions under this heading being set down at 20,904, thus apportioned: Europeans, 10,978; Asiatics, 9906; Africans, 20. During the four preceding years, with an average strength stated to have been about the same as in 1897, the admissions were as given below:—

1893	.. admissions for "palustral fever" ...	17,447
1894	... " " " " ...	13,496
1895	... " " " " ...	16,970
1896	... " " " " ...	16 416
1897	... " " " " ...	20,904

Apparently, therefore, the year under report was an exceptionally unhealthy one with regard to malarial affections. In 1897 cholera caused 161 admissions with 106 deaths among the Europeans, and 69 admissions with 52 deaths among the natives, but with the exception of beri-beri the ravages committed by the other general diseases were inconsiderable. Small-pox, chicken-pox, and measles were each represented by a case or two, chiefly among the Asiatics, the type being invariably extremely mild. Diphtheria was entirely unrepresented, and only 37 cases in all of enteric fever were treated, with five deaths, 29 of the cases occurring among the white troops and eight among the blacks. 283 Europeans and 1955 natives were under treatment for beri beri during the twelvemonth, the casualties among the former being eight deaths and 40 invalidings, and among the latter 84 deaths and 402 invalidings. The following statement showing the admissions to hospital on account of beri-beri during the preceding quinquennium would appear to point to a satisfactory diminution in the incidence of this terribly fatal disease:—

1893	.. ... admissions for beri-beri	6174
1894	... ... " " "	4994
1895	... ... " " "	5676
1896	.. ... " " "	5780
1897	.. ... " " "	2238

On the other hand, syphilis seems to be increasing considerably, the admissions which it caused having risen from 790 in 1893 to 1061 in 1897, when 11 Europeans and eight natives were invalided on account of it. In the section dealing with mortality no fewer than 25 deaths are ascribed to venereal disease, amongst the fatal causes being mentioned acute nephritis and blenorrhagic conjunctivitis (!), but in the latter instance no doubt the fatal affection supervened while the patient was in hospital for his eye complaint. Two cases of leprosy were treated during the year, both occurring in Asiatics. There was one fatal case of tetanus, the subject being a European. 35 white patients suffered from acute rheumatism, and also 16 natives; the disease must have been exceptionally mild as it gave rise to neither death nor invaliding. Three fatal cases of "tropical" dysentery occurred among the European troops. Turning to local diseases some of the entries are rather remarkable. 192 Europeans and 193 Asiatics were admitted to hospital for neuralgia; and for neurasthenia 97 and five respectively. The incidence of epilepsy was more even, the figures in this case being 24 and 22 For delirium tremens the natives show a clean sheet, but the white troops furnished 10 cases, as well as 21 of chronic alcoholism. Insolation and apoplexy were vastly more frequent among the strangers to the climate; but with regard to mental affections there was equilibrium, in either case the admissions numbering 34.

Under the head of respiratory and circulatory diseases are to be found no fewer than 947 cases of palpitation of the heart in Europeans and 1077 in natives. 101 of the former were invalided through it and also 94 natives. In each class there would seem to have been a high mortality ascribed to this symptom. According to an authority whose name is not given palpitation of the heart is but a synonym for beri-beri in an early stage of that little understood affection. Hepatic hyperæmia was treated in 115 Europeans against 19 natives, abscess following 23 times and twice respectively Finally, venereal diseases (other than syphilis) are, like the major affection, largely on the increase. In 1893 the number of cases treated was 8261; in the year under report it had risen to 10,862.

THE ANNUAL REPORT (1898) OF THE MEDICAL OFFICER OF HEALTH OF LONDON.

I.

WE announced last week that the annual report of the medical officer of health of the Administrative County of London had been published, and we referred to the pregnant remarks that were made therein in regard to the better provision of slaughter-houses in London, and the desirability of a more efficient system of meat inspection being established. We now return to this valuable report, selecting a few more equally important subjects in relation to the well-being of the metropolis.

BACTERIOLOGY AS AN AID TO DIAGNOSIS.

It is interesting to record the fact that the employment of bacteriological methods for the purpose of diagnosis is increasing in London, and Mr. Shirley Murphy writes that it is probable that these methods will in the future be more largely resorted to when doubt may exist as to the precise nature of a malady. Many of the vestries have made arrangements for the bacteriological examination of material from suspected cases of diphtheria and enteric fever. In the case of Westminster the vestry have provided at the town hall an incubator, steriliser, and microscope for the use of medical practitioners.

TRADE AND OTHER NUISANCES.

We are glad to note that a sharp look-out is maintained over trade nuisances, and under this heading, of course, comes the intolerable nuisance attributable to smoke. As will be remembered the smoke nuisance was very offensively in evidence during the year 1898 in particular, when the supply of Welsh coal failed owing to a strike. The London County Council have, we believe, not been backward in reminding authorities of their duties in this matter, and several instances of proceedings in the police-court were instituted with salutary results. Whilst we admit that the coal strike did aggravate the evil, yet we contend that the nuisance existed before, and we believe that we were among the first to point out that the Public Health Act provided a remedy, and that in general this fact was ignored by the authorities. The demand for coal by the Government may likely enough lead to a recrudescence of the evil.

The disposal of refuse has occupied a good deal of the Council's attention. The increasing difficulty, for example, which owners of manure experience in effecting its removal points to the need of this work being undertaken more largely by sanitary authorities with power to charge the owners with the cost of removal and without the need of serving notices in respect of each particular accumulation for which such charge can be made. A report was issued by the Public Health Committee in which it was recommended that steps should be taken with a view to obtaining such an amendment of the law as will give the London sanitary authorities powers of the kind just indicated. The removal of offensive refuse also appears to require further powers, that due to fish offal being under the consideration of the Public Health Committee. Failure properly to remove house refuse was the subject of indictment against some authorities. The Council decided to offer a prize for the best design of a dustcart which would enable house refuse to be removed without causing nuisance. We do not learn from the report whether the Council received any response to this invitation, but it is stated that the results of the Council's efforts to secure a weekly collection of house refuse throughout London by means of the dustcart calling at each house has been attended by considerable success. The medical officer of health concludes that there is room for hope that at no distant time all houses in London will be provided with moveable receptacles and that it will be practicable for the sanitary authorities who will be constituted under the London Government Act of 1899 to institute a daily collection of refuse throughout London and thus by better scavenging to remove one of the conditions which tend to the production of diarrhœal disease. In connexion with the disposal of house refuse it is satisfactory to observe that the method of destruction by fire is gradually being adopted. Destructors are employed and in some cases the waste-heap produced is turned to account.

FLOODING FROM SEWERS AND SEWER VENTILATORS.

The flooding of basements from sewers demands serious attention, for Mr. Shirley Murphy reports that it has again occurred during 1898. In Kensington, for example, the medical officer of health states that in times of heavy rain a main sewer has on many occasions proved inadequate and on one occasion 300 basements are known to have been flooded. Bad reports of this kind have also come from South London, Plumstead, and Charlton. Complaints have also been received respecting the smell that arises from sewer ventilators, and it is very properly suggested that more ventilators should be provided which should be carried up to a considerable height instead of being at the ground level. This provision has resulted in much benefit to the health of the localities concerned.

THE PREPARATION IN LONDON OF FOOD FOR SALE.

We are glad to see that the attention of the Council has been directed to the desirability of maintaining wholesome conditions in all places where food is prepared for the purposes of sale. An inquiry was instituted in 1898 by the assistant medical officer, Dr. W. H. Hamer, on which occasion he visited the premises of ice-cream vendors, manufacturers of Polish or Russian cheese, and butchers and sausage-makers, as well as certain restaurants, eating-houses, and fried-fish and eel-pie shops. The report showed the need for sanitary authorities to be empowered to require that food shall be kept under conditions which do not expose it to risk of contamination. In the matter of ice-cream there are grounds for justifying a claim for more complete control than in the case of other articles of food. We have repeatedly urged this fact upon the attention of sanitary authorities ever since the awful disclosures of THE LANCET Sanitary Commission in 1879 on the condition of the Italian quarter in Clerkenwell.[1] There can be little doubt that could this power be obtained we should hear little more of cases of poisoning by ice-cream. We have in particular urged that all ice-cream makers should be registered and their premises inspected from time to time with a view to control the environment, and we learn that where this has been done the results have been very satisfactory.

DISINFECTION.

A very important inquiry was made during the past official year by Dr. C. W. F. Young as to the provision of apparatus for disinfection and the methods of disinfection practised in the London sanitary districts and his report appears at length in the appendix. There are instances where the disinfecting equipment cannot be considered as satisfactory. In several districts the use of formaldehyde for the disinfection of rooms has superseded the use of sulphur dioxide. According to the medical officer of health of the Strand District formic aldehyde as a gas or in the form of spray gives the best results for room disinfection and he recommends its use in his district. In the large majority of London districts, however, the use of sulphur dioxide is depended on, chlorine being only exceptionally employed.

WATER-SUPPLY.

Several accounts of the failure of constant supply of water from August to the early part of December were contributed by the medical officers of health of the districts supplied by the East London Waterworks Company, but notwithstanding the conditions produced by the insufficiency of the water-supply it does not appear that the medical officers of health associate increased mortality with this insufficiency. The resolutions adopted by the Council in regard to the future supply of London are embodied in this section of Mr. Shirley Murphy's report, and now that the report of the Royal Commission on Water-supply has at length been issued it will be interesting to see what attitude the Council will adopt in regard to their proposal to augment the water-supply from a watershed in Wales. The Royal Commission, it may be noted, while seeing something attractive in the scheme of bringing water from the Welsh mountains, deem the expense of such an undertaking to rule the proposal out of court. But they add the curious remark that "one would be glad if it were possible now to secure a watershed to be used hereafter if London should require it."

---

[1] THE LANCET, Oct. 18th, 1879 p. 593.

THE PLAGUE AT KOLOBOVKA IN 1899.

So little has up to the present time been published concerning the outbreak of plague at the mouths of the Volga in the summer of last year that a paper describing in full detail the principal features of the outbreak is unusually welcome. Such a paper has recently been published by Professor A. M. Levin,[1] who was among the first group of medical men who investigated the epidemic on behalf of the Russian Imperial Plague Commission. Though Dr. Levin did not reach the scene of the outbreak until it was nearly over and was only enabled to see three cases of the disease, he succeeded in obtaining a sufficiently complete account of the preceding cases to admit of his reconstructing the story of the epidemic from beginning to end. The following are the principal facts which his inquiries brought to light.

Kolobovka, the scene of the outbreak, is a village in the Tsaref *uyezd*, or district, of the government of Astrakhan. It lies on the raised left bank of the river Akhtuba, the principal easterly mouth of the Volga. It contains some 457 *dvors*, or courtyards, round which the dwellings are built, and a population estimated at about 3500 souls. The people are Great Russians, members of the Orthodox or Eastern Church, and are occupied principally in agriculture and sheep-rearing. The fields belonging to the peasants here are mostly situated in the steppes at a considerable distance from the village; and consequently during the season of field work all the able-bodied inhabitants—both male and female—go out into the steppes, where they live for the time in small huts or *izbushki*. Some of these are built half underground, and they are scattered irregularly over the steppes at considerable distances from each other. In the meantime the village is left with only the old, the sick, and the children for its population—with the exception that every few days the villagers at work in the steppes pay a brief visit to their homes in the village—principally, apparently, to obtain food supplies.

Up to July 16th (28th) of last year the health of Kolobovka appeared to be quite normal. There was no unusual mortality and no signs of the presence of any infectious disease. But on the date named a deaf-and-dumb woman, named Maria Semakina, aged 35 years, while at work in the fields fell ill with fever and cough and expectoration of blood. She was brought back to the village and died there on July 21st (August 2nd). It was not until the 27th of July that a medical man visited the village and consequently there is some uncertainty about the succeeding cases; but it was gathered that on the day following this first death the woman who kept the house where Maria Semakina lived also fell ill with fever and spitting of blood. She died on July 25th (August 6th). On that day her son developed the same symptoms, with the addition of pain in the chest, and died in less than 24 hours after their onset. In the meantime other persons had been attacked with the disease, but all were either relations of the first patient or had attended her funeral. Thus on July 22nd (the dates henceforth mentioned are all according to the Old Style) an old man of 70 years of age was attacked with fever, vomiting, pains in the chest, and spitting of blood, and died on the 25th. Four other persons sickened on the 25th, 26th, 26th, and 30th of the month respectively, and all with practically the same symptoms. All these patients were of comparatively advanced years—a fact no doubt due to the absence of the younger villagers for the reasons explained above.

In all 24 persons were attacked with the disease and no less than 23 died from it. The case-mortality was therefore 96 per cent.—a figure so high that, as it is pointed out, it alone seemed to point to a diagnosis of plague, few, if any, other diseases presenting so high a degree of fatality. The rapidity of its course was equally striking. Of the 23 deaths, six occurred on the first day of illness, three on the second, nine on the third, three on the fourth, and two on the fifth. The most prominent symptoms pointed to a severe lung affection. The patients complained of pain in the chest, cough, and expectoration containing a good deal of blood. The sputa are described as "watery mucous," and as coming up in large quantity and with great ease. On examining the chest it was usually found that a few scattered dry or moist sounds could be heard, and only in a few cases were crepitations present and these were unaccompanied by any notable dulness. Dr. Levin, who was a member of the first Russian Plague Commission sent to India and had seen many cases of pneumonic plague in Bombay, found that the symptoms presented by the patients in Kolobovka were identical with those of the pneumonic plague patients seen by him in the Indian city. The other principal symptoms were fever, marked mental disturbance, a white, furred tongue, rapid pulse, and in a few cases petechiæ on the skin. The petechiæ differed from those of typhus fever in being of a darker and more purple colour than those met with in that disease.

While the large majority of the patients developed the disease in its pneumonic form, in a few the disease appeared in its primary bubonic form. One had a "bubo in the right groin," another a "very tender enlarged gland in the right axilla," and a third a "rather tender swelling in the right groin and enlargement of cervical glands." Apparently these were the only three cases of bubonic plague, and the remainder, 21 in number, suffered from the pneumonic variety of plague. The diagnosis was confirmed by the isolation from the tissues of some of the later patients of bacilli which gave all the reactions of Kitasato's plague micro-organism. The laboratory experiments to identify the bacillus were carried out partly in Astrakhan and partly in Fort Alexander I.—the island near Cronstadt which, as already described in the columns of THE LANCET,[2] has been converted into a laboratory for the preparation of plague antitoxin.

The origin of this outbreak of plague has not as yet been satisfactorily explained and its explanation is surrounded by almost insuperable difficulties. Just as was the case in Oporto, in Alexandria, in Mauritius, in Madagascar, in Bombay, and, indeed, almost in every place to which plague has spread in recent years, no direct importation of infection from a pre-existing focus of the disease could be traced. Kolobovka lies on a high road upon which there is a pretty lively traffic to and fro between the delta of the Volga and the town of Tsaritsyn further up the river. Among the people constantly travelling on this road are many Persians and Persian Tatars who every year come in large numbers from Enzeli to Astrakhan to seek work. Some years ago plague was endemic in Persia, but nothing has been heard of the disease there for the past 15 or 20 years. Dr. Levin has made an alternative suggestion as to the origin of the infection. Kolobovka, he points out, lies in the Kalmuck steppes, which extend from the left bank of the Volga to the Ural river. The steppes are inhabited principally by Lamaite Kalmucks, whose praying-places can be seen at intervals on the banks of the Volga. From private letters from the Russian consul-general in Ourga, in northern Mongolia, it was ascertained that among the pilgrims who yearly visit the Buddhist shrines in northern and north-eastern Mongolia are a considerable number of Kalmucks from these very steppes between the Volga river and the Ural river. There is a well-known endemic centre of plague in eastern Mongolia. May not, it is asked, some Kalmuck pilgrims returning from that country have brought with them the infective material of plague? It is impossible here to discuss in full the considerations which favour (or the reverse) this view as to the origin of the Kolobovka outbreak. It can scarcely, however, fail to strike the reader that there are very great difficulties in accepting this explanation. The plague centre in Mongolia is removed from the Volga river by some 70 degrees of longitude—a distance which may be roughly estimated at about 4000 miles. The journey from the one to the other would of necessity occupy many months, and it is not easy to understand why the plague infection, after being carried over that long distance, should have attacked, not the Kalmuck pilgrims themselves or their relations, but the Christian population of a Russian village. A more plausible explanation, though one still fraught with many difficulties, might be found in the importation of infection from Russian Central Asia, where a very severe outbreak of plague occurred in the late summer and autumn of 1898. The village of Anzob, the chief centre of that outbreak, is scarcely more than 1000 miles from Kolobovka, and there is a pretty constant traffic of persons from that part of Russian Central Asia to Astrakhan and the Volga provinces. No proof, however, of such a method of transportation of infection is forthcoming, and any explanation of the sort must for the present rest entirely on somewhat fruitless speculation.

---

[1] Vratch, [illegible] No [illegible], p [illegible]

[2] THE LANCET, Sept. [illegible], [illegible], p [illegible]

To return to the facts of the Kolobovka outbreak, it is stated that no mortality among rats or other rodents was observed in connexion with it. An experienced veterinary surgeon, Mr. Tartanovski, was specially deputed to investigate the matter, and though he examined over 3000 bodies of small rodent animals he found no traces of suspicious disease in any of them.

The measures undertaken to check the epidemic were of a radical character. The whole village was surrounded by a cordon, which included also the steppes in the neighbourhood. The circle had a circumference of about 135 versts or 90 miles. The cordon was at first kept by the local inhabitants, but later by Cossack troops. The village was divided into sections and twice daily a house-to-house visitation was made in each section. All patients found were removed to hospital and the "contacts" segregated in another building specially set aside for them. The hut in which the case had occurred was closed and it and the earth round it were drenched with lime. Formalin and carbolic acid were also largely employed as disinfectants and the extent to which they were used may be gathered from the statement that as many as 700 litres of formalin and 150 poods (equivalent to about 6000 pounds) of carbolic acid were got through before the epidemic was over. Inoculation with Haffkine's prophylactic was freely offered to the villagers, and though nothing in the way of persuasion or threats was used some 4000 persons were voluntarily inoculated in the course of two weeks, including the medical, nursing, and disinfecting staffs. This practically represented the entire population of the village and of the neighbouring steppes, with the exception of some 40 persons who either declined or who were advised not to undergo the operation on account of their age or health. It would have been interesting to know whether this inoculation of the entire community was the principal cause of, or a decisive factor in, the extinction of the epidemic, but upon this point the article under notice throws no light.

THE WAR IN SOUTH AFRICA.

The eyes of English-speaking people are all turned in the direction of their thoughts, and their thoughts, it is needless to say, are focussed on the dramatic events now taking place in a limited part of Natal. General Buller has devised a new and bold strategical scheme for the relief of Ladysmith. His forces are now on a march from which there is "no turning back"; their progress so far has been slow but sure, and we must be content to possess our souls in patience and await further developments. There is no concealing the fact, however, that news of the attack on Spion Kop is awaited with keen anxiety. At the time of writing the bare fact of the position having been captured has reached London, and we are in ignorance both of the cost of our victory and of its probable results.

We are glad to notice the change of tone which is taking place in the press and among the people generally in regard to the Government and the military authorities. Miscalculations and mistakes have, no doubt, occurred in the course of this campaign and it is quite right and fitting that everything connected with the war should hereafter be reviewed and subjected to the strictest criticism, but it strikes us as neither just nor generous to do this at the present moment on very incomplete information or to shut our eyes to the extreme difficulties which have had to be encountered or to the great and successful efforts that have been made to overcome them. After all, it may be truthfully affirmed that never before have 120,000 troops been transported in the same space of time to a destination some 6000 or 7000 miles distant from this country; there is no other Power in the world which could have accomplished it. Never before has an army been so well furnished and equipped with all the requirements of field service. We have only to compare the present expedition with those of other countries or with any previous expedition from this island to recognise the contrast, so striking and remarkable has it been. Not only had the Boers matured all their plans and selected their own time for declaring war at two days' notice, but the great extent and the geographical and topographical obstacles of a country, every inch of which was well known to them, have to be borne in mind; and the Boers had, moreover, the best and most ubiquitous intelligence department in the world at their disposal—namely, spies and people friendly to their cause distributed everywhere. Even many of our hired sick-bearers in the field deserted to the enemy. As to any attempt at a military surprise on our part it was merely a farce and a pantomime, for it almost invariably turned out that, instead of being surprised, our foes had, on the contrary, carefully prepared some trap or ambush to surprise us, and we had consequently to buy our experience of Boer tactics and wariness at a heavy cost. But the great difficulty, after all, which had to be surmounted in this campaign was the military situation which existed in South Africa at the time of the arrival of our reinforcements there and the emergent political necessity which this created—namely, the relief of besieged British garrisons. The British generals and troops found themselves, too, face to face with new and hitherto unprecedented conditions of warfare. We feel confident that a calm and impartial consideration of all the circumstances will bring about a very different view to that which now apparently obtains and to which our checks and want of success have hitherto given rise. It is no doubt the consciousness of all this on the part of the Government that causes the Cabinet to hail the opening of Parliament with gladness. It is easy enough to be wise after the event. The Government were blamed not long ago for doing too much and for driving the Boers into war, whereas it is now blamed for not having acted with sufficient promptitude and for not having done half enough when it did act.

Troops in large numbers, field batteries, and hospital ships are arriving at the Cape or are being sent out from this country, and large batches of sick and wounded are returning from the scene of war and being forwarded on arrival to Netley, where every preparation has been made for their reception. In addition to the arrangements that have been made at our large military stations, proffers of hospital accommodation for our wounded and convalescent officers and soldiers are being made to the War Office from all sides. If there is some abatement (for which we confess we are not at all sorry) of enthusiasm in the "send off" of troops from this country there is no sign of it in our colonies, for at Winnipeg, Montreal, Halifax, Sydney, Melbourne, and Adelaide the embarkation of troops gives rise to great popular excitement.

The Secretary for War has accepted the offer of Mr. Van Alen (an American gentleman now resident in London) to provide a section of a field hospital, complete in every respect, for service in South Africa under the medical superintendence of Captain E. Powell, R.A.M.C. A hospital for the Imperial Yeomanry is being fitted out and all appointments on its medical and surgical staff have been already filled up. These include Dr. John Wichenford Washbourn (physician and lecturer at Guy's Hospital and physician to the London Fever Hospital), Mr. Raymond Johnson (assistant surgeon to University College Hospital and to the Victoria Hospital for Children), and Mr. F. Newland-Pedley (senior dental surgeon to Guy's Hospital and lecturer on dental surgery in the Guy's Hospital Dental School).

The Portland Hospital, which arrived at Cape Town on Dec. 26th, forms an independent section of No. 3 Hospital at Rondebosch and is in complete working order. It is very gratifying to read that the staff of the hospital have received great help from the principal medical officer and everyone connected with the Royal Army Medical Corps, and that no difficulties of any sort have arisen. The labours of the medical corps in the field, along the lines of communication, at railway junction depôts, and at base hospitals are very arduous, and the fearless conduct of medical officers in aiding and bringing away the wounded from the firing line at the various battlefields is, we read, "in everyone's mouth."

The reported casualties in the various forces which are now on the march or fighting their way towards Ladysmith have not so far been large considering the numbers engaged and the severity of the fighting, but these must, it is feared, reach a very much higher number when the more strongly held positions and lines of entrenchments held by the Boers have to be attacked and taken. We are writing before information has reached us concerning the cost of capturing Spion Kop. The fighting columns are accompanied by strong parties of hired stretcher-bearers as a supplementary aid to the regularly organised bearer columns, field hospital transport, and usual field hospital equipment. The garrison of Ladysmith have not only held out nobly but they have exhibited conspicuous boldness and enterprise in their various successful encounters with the besieging forces. The sick-rate and death-rate—mainly from enteric fever and dysentery—which have not been high, are nevertheless mounting up and are bound to do so under the conditions obtaining at Ladysmith, and the relief of the garrison is therefore becoming a matter of urgent necessity. Although the occupation of Ladysmith has exercised a very unfortunate influence on the intended conduct of the campaign it was, nevertheless, unavoidable under the circumstances, and from another point of view it must not be forgotten that General White's troops have performed a signal service in having occupied the Boers and defeated all their attacks and in that way delayed and completely frustrated any intention they may have had to get to the south-eastern seaboard, where their presence in force might have had a very serious and damaging effect upon British troops disembarking at Durban. It seems to our non-military mind that, after all, the greatest source of embarrassment, loss of life, and casualties has arisen from Kimberley, and our attempts (which have so far proved futile) to relieve it. It is astonishing how little we seem to know of the strength of the Boer forces in the field, of their casualties in their various engagements with us, or of their losses by sickness. Their "censorship" at any rate is uncommonly strict.

ITALY AND OUR SOUTH AFRICAN WOUNDED.

Our Rome correspondent writes under date Jan. 22nd:—"To the steadily lengthening list of Italian hotels whose proprietors announce their alacrity to receive gratuitously or at a nominal charge those of the wounded British officers in South Africa who would fain pass their convalescent period in Italy's genial lake country or on her sunny seaboard I can add the 'Albergo delle Sirene' at Porto d'Anzio on the Latin shore. Signor Tommassetti, its proprietor, has just intimated to the British Government that it may freely use his commodious establishment for the purpose indicated, and I am sure the kindly offer will be accepted in the same spirit in which it is tendered. The rigours of a northern winter or the vicissitudes of a northern spring, trying even for the healthy, must be especially so to the convalescent from wounds received on the battlefield or from sickness contracted during service in the open, and nowhere could exemption from such adverse climatic conditions be more completely secured than on that lovely stretch of coast where, as we learn from Cicero and the Younger Pliny, the Roman patrician delighted to make his *villeggiatura*. The combination of sea air wafted shorewards from the blue rollers of the Mediterranean with the sun-tempered breezes from the Alban and Volscian hill-country is delightfully reinforced or mollified by the exhalation from the pine woods and the laurel groves which line the coast or extend inland, while the surrounding associations or impressions, historic or artistic, are of themselves fitted to be a salutary 'alterative' to those of the South Africa 'veldt' or 'kopje,' redolent of a bogus, if militant, Puritanism. But not more welcome can such an improvised 'sanatorium' be to the wounded or invalided officer than the kindly, hospitable spirit which proffers it must prove to the nationality thus favoured—target, as the said nationality has been, and still is, for every missile (spoken, written, or engraved) which foreign envy, hatred, and uncharitableness have at command. Italy, to her honour be it said, is the most considerable among that minority of European Powers which judges British intervention in South Africa with a 'benevolent neutrality,' and when the present war shall have reached its inevitably triumphant issue for the forces of constitutional right and economic prosperity her attitude will be remembered—not to her disadvantage—in common with that of Denmark, of Norway, and of Greece. Even as it is she is reaping the fruit of her chivalrously courteous, aye, of her cordially sympathetic, conduct. We do not read of English ladies alighting at an Italian hotel and having to leave that very day after finding the *salle de lecture* littered with journals caricaturing, with equal coarseness and malignity, the person of the most venerable and esteemed of European monarchs. Such incidents are reported to me from the Alpes Maritimes which have their reward in seeing the victim of such base insults choose the Ligurian Riviera for her vernal *villeggiatura*, and in so doing attract to the many delightful health resorts on that favoured seaboard those English-speaking guests whose patronage their French rivals can so little spare. Not only so, but much further south Italy will profit at the expense of her supercilious neighbour as hostess to the Anglo-American world. From Malta I learn that arrangements are on foot for the reception of H.R.H. the Prince of Wales when his contemplated yachting cruise in the Mediterranean will take him to that island, whence, I am further informed, His Royal Highness will touch at Civita Vecchia *en route* to Rome to witness the Easter ceremonies specially ordered for the Holy Year. All this, I repeat, is already the subject of envious anticipation and bitter comment in French journals; while Italy will show her appreciation of the attention her kindly attitude evokes by doing her best to retain the preference now being vouchsafed to her, and so increasing her attractions or minimising her deterrents for the English-speaking world as to convert an occasional into a permanent—and that an increasingly profitable—*clientèle*."

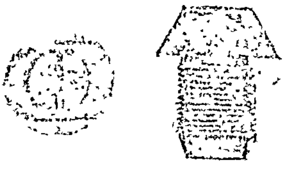
AN AMERICAN SURGEON'S SYMPATHY FOR ENGLAND.

A former American pupil of St. Bartholomew's Hospital writes from near Chicago to one of his old teachers to say that in order to show his good will and his appreciation of the many favours and advantages received from friends while in England he will be pleased to serve in the capacity of surgeon or assistant surgeon during the war in South Africa. He will be ready, at six hours notice, to go as an American volunteer, take the oath of allegiance, or become a British subject, and serve anywhere under the Union Jack that duty needs or generals direct. He would consider such an appointment the greatest honour of his life.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

With the exception of the facts that all cases are progressing favourably and that several are being sent home in the *Dunera* and other transports my news this week is of the scantiest. No. 4 General Hospital has been ordered off to the Natal side and will probably go to Estcourt, where later, and I dare say before you get this, the services of its staff will be required. The Portland Hospital arrived in the *Majestic* on Friday night, Dec. 29th, and is to be established, so we hear, at Rondebosch, thus adding to the accommodation already here—for Rondebosch is only a very short distance from Wynberg. We are gradually drafting off the convalescents and getting the wards ready again for the reception of cases that will be coming down—probably in a few days. A new operating room is being built for the use of the officers' hospital, so that will obviate the necessity of performing operations in the building, and be a great convenience to everyone concerned.

Your readers may like to hear of a good case. The wound was of the abdominal walls caused by the screw of a shell which entered about an inch above the umbilicus and passed round the abdomen, emerging on the left side about one and a half inches above the crest of the ilium. I think there was little doubt but that the missile entered the cavity of the abdomen and emerged again almost immediately at the exit wound, but with the exception of a considerable amount of shock the patient (an officer) has made an uninterrupted recovery. I append a rough drawing of the screw. There was no local peritonitis in this case.



We shall have a large consignment of wounded officers to send home in the *Princess of Wales*, the arrival of which here is daily expected. These, of course, will be the more serious cases that will require a certain amount of dressing on the way and to whom a comfortable hospital ship with all necessary appliances and nursing will be a necessity. At present in both hospitals here there are about 750 sick and wounded, some of whom of course will soon be fit for duty again, but others will have to go to Netley. This does not include the patients in No. 3 General Hospital at Rondebosch. Arrangements have been made by the Red Cross Society for convalescent officers to be accommodated at the Mount Nelson Hotel, which is a fine building situated on the high ground above Cape Town. This of course lessens the tedium of a prolonged convalescence, and as the "cuisine" and internal arrangements are much more perfect and up to date than can be given them in hospital it is a great boon and is much appreciated. The strain that has been thrown on our hospital accommodation for so large a number of wounded officers has been very great, yet I am happy to say that, with a few exceptions, all have expressed themselves as being well pleased with the provision made for them. Of course it should be borne in mind that the accommodation and equipment of even a general hospital will not bear the influx of three times as many wounded officers as the regulations provide for, but up to the present time we have met the rush, and the fact that we have had so far only two fatalities out of nearly 100 officers treated speaks for itself. I may add that both the fatal cases referred to were in a very critical state when they were received. All the wounded Boers, with the exception of one in whom it was necessary to amputate the thigh for extensive disorganisation of the knee-joint, have left hospital, and I believe are at present on their way to St. Helena, where they will be out of harm's way and be well looked after. The ambulance trains have gone up country again, and as they are the "stormy petrels" we must be prepared for more work at any moment.

Wynberg, Jan 3rd.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6729 births and 5552 deaths were registered during the week ending Jan. 20th. The annual rate of mortality in these towns, which had been 30·9 and 29·1 per 1000 in the two preceding weeks, further declined to 24·9 last week. In London the rate was 26·9 per 1000, while it averaged 23·7 in the 32 provincial towns. The lowest death-rates in these towns were 11·2 in Oldham, 14·5 in Cardiff, 15·3 in Plymouth, and 17·0 in Huddersfield; the highest rates were 30·4 in Sunderland, 31·8 in Norwich, 32·0 in Liverpool, and 32·2 in Nottingham. The 5552 deaths in these towns included 443 which were referred to the principal zymotic diseases, against 503 and 453 in the two preceding weeks; of these 121 resulted from measles, 115 from whooping-cough, 96 from diphtheria, 39 from "fever" (principally enteric), 35 from scarlet fever, 35 from diarrhœa, and two from small-pox. No fatal case of any of these diseases occurred last week in Derby; in other towns they caused the lowest death-rates in Croydon, Plymouth, Swansea, Huddersfield, and Gateshead, and the highest rates in Wolverhampton, Liverpool, Blackburn, Preston, and Sheffield. The greatest mortality from measles occurred in Wolverhampton, Salford, Preston, Sheffield, and Hull; from scarlet fever in Preston and Halifax; and from whooping-cough in Portsmouth, Liverpool, Bolton, Salford, and Newcastle. The mortality from diarrhœa and from "fever" showed no marked excess in any of the large towns. The 96 deaths from diphtheria included 40 in London, 14 in Sheffield, eight in Liverpool, five in Leeds, and four in Manchester. One fatal case of small-pox was registered last week in Liverpool, and one in Hull, but not one in any other of the 33 large towns. There were 21 cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday last, Jan. 20th, against numbers increasing from five to 18 at the end of the four preceding weeks; five new cases were admitted during the week, against two, one, and 10 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2441, against numbers decreasing from 3578 to 2560 on the nine preceding Saturdays; 208 new cases were admitted during the week, against 161, 186, and 180 in the three preceding weeks. Influenza was certified as the primary cause of 208 deaths in London last week. The deaths referred to diseases of the respiratory organs in London, which had been 1221 and 994 in the two preceding weeks, further declined to 728 last week, but were 41 above the corrected average. The causes of 84, or 1·5 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Plymouth, Cardiff, Nottingham, Oldham, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Burnley, Preston, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25·6 and 23·0 per 1000 in the two preceding weeks, rose again to 23·3 during the week ending Jan. 20th, but was 1·6 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 19·3 in Paisley and 21·7 in Dundee to 26·6 in Greenock and 27·0 in Perth. The 721 deaths in these towns included 32 from measles, eight from scarlet fever, eight from whooping-cough, seven from diphtheria, seven from diarrhœa, and six from "fever." In all 68 deaths resulted from these principal zymotic diseases, against 64 and 65 in the two preceding weeks. These 68 deaths were equal to an annual rate of 2·2 per 1000, which was 0·2 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had decreased from 37 to 20 in the four preceding weeks, rose again to 32 last week, and included 19 in Glasgow, eight in Dundee, and four in Paisley. The deaths from scarlet fever, which had declined from eight to four in the four preceding weeks, rose again last week to eight, of which four occurred in Glasgow and three in Edinburgh. The fatal cases of whooping cough, which had been nine and 14 in the two preceding weeks, declined again to eight last week, and included four in Glasgow and two in Perth. The deaths from diphtheria, which had been three and five in the two preceding weeks, further rose last week to seven, of which three were registered in Glasgow and two in Edinburgh. The seven fatal cases of diarrhœa showed a marked decline from recent weekly numbers and included three in Glasgow and two in Dundee. The deaths referred to different forms of "fever," which had been two and six in the two preceding weeks, were again six last week, of which three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 253 to 203 in the three preceding weeks, further fell to 198 last week, but were 45 above the number in the corresponding period of last year. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 50·3 and 49·4 per 1000 in the two preceding weeks, further declined to 44·0 during the week ending Jan. 20th. During the past four weeks the death-rate in the city has averaged 46·4 per 1000, the rate during the same period being 33·1 in London and 23·1 in Edinburgh. The 295 deaths registered in Dublin during the week under notice were 36 below the number in the preceding week, and included 22 which were referred to the principal zymotic diseases, against 18 and 31 in the two preceding weeks; of these nine resulted from measles, six from diarrhœa, three from whooping-cough, two from diphtheria, two from "fever," and not one either from small-pox or from scarlet fever. These 22 deaths were equal to an annual rate of 3·3 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·4 in Edinburgh. The deaths referred to measles, which had been 10 and 18 in the two preceding weeks, declined again last week to 9. The fatal cases of diarrhœa, which had been one, two, and three in the three preceding weeks, further rose to six last week. The deaths from whooping-cough, which had decreased from three to one in the five preceding weeks, rose again last week to three. The two deaths from diphtheria showed a decline from the number in the preceding week. The deaths referred to different forms of "fever," which had been five in each of the two preceding weeks, declined to two last week. The 295 deaths in Dublin last week included 31 of infants under one year and 105 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Seven inquest cases and five deaths from violence were registered, and 98, or nearly a third, of the deaths occurred in public institutions. The causes of six, or more than 2 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

DEPUTY Inspector-General of Hospitals and Fleets James Hamilton Martin, D S O., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. The undermentioned Fleet Surgeons have been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet:—Gerard James Irvine and Henry Thompson Cox. The undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet:—Richard Edmund Biddulph, Gilbert Kirker, William Tait, and Joseph Crowley.

The following appointments are announced:—Staff Surgeons: William J Colborne to the *President* for Medical Department; Henry B. Beatty to the *Gladiator* and afterwards to the *Royal Arthur*, for the *Katoomba* and for medical charge at Sydney Reserve Depôt; and E. R. D. Fasken to the *Medusa*. Surgeon: J. McElwee to the *Boscawen* for the *Agincourt*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. R. Greenhill, A.M.S., assumes medical charge of the Station Hospital, Gosport. Major D. Stiell proceeds to Woolwich for temporary duty. Captain P. H. Whiston is appointed to the Medical Staff in the Home District, Lieutenant G. J S Archer proceeds to Woolwich for duty with No. 5. Stationary Hospital,

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Edward Cureton resigns his commission. Surgeon-Captain T. Tinley, 1st East Riding of Yorkshire Volunteer Artillery, to be Surgeon-Major.

VOLUNTEER CORPS

Artillery: 1st Edinburgh (City): Surgeon-Lieutenant-Colonel J. J. K. Duncanson resigns his commission, with permission to retain his rank and to wear the uniform of the corps on his retirement. 1st Forfarshire: Horace Crakanthorp Colman to be Surgeon-Lieutenant. 1st Norfolk (Eastern Division, Royal Garrison Artillery): John Charles Reynolds Robinson to be Surgeon-Lieutenant. *Royal Engineers*: 1st London: John Charles Jackson to be Surgeon-Lieutenant. *Rifle*: 19th Middlesex: Surgeon-Lieutenant M. Richards resigns his commission.

TRANSVAAL WAR NOTES.

Princess Christian has signified her willingness to become honorary president of a fund the object of which is to collect subscriptions for providing comforts for non-commissioned officers and men of the Royal Army Medical Corps. The following ladies will act on the committee of this fund: Viscountess Knutsford, Lady Wantage, Lady Rothschild, Lady White, Lady MacCormac, Lady Coventry, Lady (Douglas) Powell, Lady Duckworth, Lady Brunton, Lady Broadbent, Mrs Pye-Smith, Mrs Pearce Gould, Mrs. Clutton, Mrs. Percy Kidd, Mrs. Reynolds Ray, Mrs. Dawson Williams, Mrs. T. Bryant, Mrs T Barlow, Mrs. Goodhart, Mrs. Hale White, Mrs. Walsham, Mrs. F. Taylor, Mrs. David Lees, Mrs. Fripp, Mrs. Vesey Holt, Mrs. Charters Symonds, Mrs. Jameson, Mrs. Muir, Mrs Johnson, Mrs. McPherson, Mrs. J. B. C. Reade, Mrs J. B Hamilton, Mrs. Charlton, Mrs. C. White, Mrs. John Anderson, and Mrs. Bourke. Miss Maxwell-Muller, late lady superintendent in the Indian Nursing Service, will act as honorary secretary and will receive subscriptions and donations at the office of the fund, 100, Victoria-street, S W.

Mr. J. Paul Bush, honorary surgeon to the Bristol Royal Infirmary and senior surgeon to the Bristol Constabulary, has been appointed senior civil surgeon to the Princess Christian Hospital now being fitted for service with the troops in South Africa and will be leaving about the middle of February.

The Queen has sent £100 to the committee of the Imperial Yeomanry Hospital for the purpose of equipping two beds.

The *Times* says: "The recent gifts to the Permanent Homes for Discharged Soldiers which the building trades propose to erect on the site presented by Lord Pirbright include the following: Lord Penrhyn (Penrhyn Quarries), 10,000 slates; Mr. Assheton Smith (Dinorwic Quarries), 10,000 slates; Messrs. George Trollope and Sons, doors, casements, and linings for one home; Messrs. T. and W. Farmiloe, the entire white lead, colour, oils, varnish, &c., for the homes; Messrs. G. B. Kent and Sons, the entire paint, toilet, &c., brushes; Messrs. Carter and Aynesley, the whole of the locks; the Mural Decoration Company, 500 yards of partitions; Mr. F. J. Ebner, the wood-block flooring for the ground floor of three homes; Messrs. D. Anderson and Son and Messrs. J. C. Broadbent and Co. (jointly), the whole of the slag wood; Messrs. Twyfords (Limited), the sanitary fittings for one home. Communications regarding the homes should be addressed to No. 1, Waterloo-place, Pall-mall."

In addition to those mentioned last week the following appointments have been made to the staff of the Imperial Yeomanry Hospital: Dr. Hamilton A. Ballance, assistant surgeon to the Norfolk and Norwich Hospital; Mr. William Turner, assistant surgeon to the Westminster Hospital; Mr. Wallace C. G. Ashdowne, surgical registrar of St. Mary's Hospital; Dr. J. B. Christopherson, demonstrator of anatomy, St. Bartholomew's Hospital; Dr. Andrew Elliot, medical registrar, West London Hospital; and Dr. H. W. Saunders.

The staff of the Langman Hospital is now complete. Mr. Robert O'Callaghan is surgeon-in-chief and Mr. Charles Gibbs, assistant surgeon to Charing-cross Hospital, is surgeon; Mr. H. J. Scharlieb, anæsthetist to University College Hospital, is assistant surgeon and anæsthetist; Dr. Conan Doyle is medical secretary and registrar; and five senior students of University College Hospital are going as surgical dressers. Lieutenant Archie Langman is secretary and treasurer, while Major O'Connor Drury, R A.M.C., is the army medical officer in command.

Lieutenant-Colonel W. A. May, R.A.M.C., has been appointed principal medical officer, and Major J. W. Jerome, R A.M C., medical officer, to the 8th Division for service in South Africa.

A committee of Danish farmers have sent to Her Royal Highness the Princess of Wales 12,000 boxes of butter for distribution among sick British soldiers in South Africa.

We learn that several private villas in Madeira have been placed at the disposal of the War Office for the use of convalescent soldiers.

The Mafeking correspondent of the *Times* in a telegram dated Jan. 3rd says.—"I have interviewed Surgeon-Major Anderson, an Imperial Service officer sent out by the Director of Hospitals to Colonel Baden-Powell's force, who authorises me to say that the wounds inflicted were altogether different to previous experience in Egypt and in India and that it was impossible that they could have been produced by Martini or Mauser bullets, though perhaps they might have been caused by Snider ones, but from a scrutiny of the wounds made while dressing them in hospital here he has no doubt in his own mind that bullets of an explosive character were used by the Boers."

The London County Council having placed the house of the late Sir Spencer Wells at Golder's Hill, Hampstead Heath, at the disposal of a Hampstead committee for the purpose of establishing a convalescent home for wounded soldiers, an appeal has been made to the residents of Hampstead for £1000 to equip Golder's Hill as a convalescent home for the Brigade of Guards and Household Cavalry and place it at the disposal of the military authorities.

The Kent and Essex General Investment Company have offered to the War Office the use of Parrock Hall, Gravesend, rent free, for 12 months, as a home for the sick and wounded from South Africa.

Mr. J. W. Morris has presented a screen to the American Ladies' Hospital Ship Fund. The screen will be raffled for and the entire proceeds will be given to the *Maine* Committee. The screen can be seen free between 10 A.M. and 6 P.M. on other days and from 10 A.M. till 1 P.M. on Saturdays at 17, Berners-street, Oxford street, W.

DEATHS IN THE SERVICES.

Major Charles Pope Walker, R.A.M.C., at Ladysmith from dysentery, on Jan. 5th, aged 41 years. He entered the medical service of the army as a captain in the Royal Army Medical Corps in 1886 and in 1887 he went to India and was attached to an English regiment serving in Quetta and afterwards in the North-West and Central Provinces.

In 1892 he returned to England and was then attached to the Guards in Ireland. In 1895 he served in the Mauritius, where he remained until 1898, when he went to the Cape and afterwards to Natal. In November, 1899, he proceeded with the troops to the front and had charge of the hospital at Dundee and was present at the battle of Elandslaagte, afterwards retiring with the forces from Dundee to Ladysmith, where he rendered valuable medical services. He obtained the rank of Major in July of last year.

OSMAN DIGNA.

We cannot forbear noticing the reported capture of Osman Digna, whose name has figured so prominently for some time past in connexion with the military history of the Soudan. It appears that he has been in hiding in the hills near Tokar, where he was captured, and that he was taken to Suakim, whence he will be conveyed to Suez by the Government steamer *Behera*. Osman Digna has had a most adventurous life and his name must be well known to all—especially to medical officers and others who took part in the late Anglo-Egyptian military expeditions to the Soudan. That he will be kept in safe custody somewhere goes without saying, but we trust that this precaution will not be inconsistent with his being treated very mercifully now that he can do no further harm He must be a brave, as he certainly is a remarkable, man.

THE EXTERMINATION OF THE MALARIAL MOSQUITO.

Dr. Cook, health officer, Calcutta, has made a proposition to employ two men to exterminate malarial mosquitoes by using kerosene oil in the pools where they breed.

Correspondence.

"SOME POINTS IN THE NATURAL HISTORY OF UTERINE FIBROIDS."

To the Editors of THE LANCET.

SIRS,—I have read with a great deal of interest Dr. Champneys' address on this subject published in THE LANCET of Jan. 20th. There are two points which seem to be especially important. The first is the conclusion that the mortality of fibroids apart from operation is represented by a small decimal—viz, 0 000138 per cent. The evidence adduced in support of this does not seem to me to be quite convincing. This percentage is apparently obtained by finding that the number of female out-patients at St. Bartholomew's Hospital from 1866 to 1898 was 2 160,112 and that in that time only three cases were met with in the post-mortem room in which death occurred from fibroids apart from operation. If I understand the argument rightly, from this Dr. Champneys asks us to conclude that the mortality apart from operation is three in 2,160,112, or 0 000138 per cent. There does not seem to me to be any necessary connexion between the number of fatal cases met with in the post-mortem room and the number of cases of uterine fibroids ending fatally in that large number of female out-patients. As we all know, the life-history of fibroid tumours of the uterus is generally a long one—a matter of many years. A patient with uterine fibroids may attend the out-patient department for a time, may be relieved by medical treatment for a time, and may cease to attend; she may become an in patient and be relieved by medical treatment and rest, and may go out. If her illness at some subsequent time takes on an acute and dangerous phase from hæmorrhage, sloughing, and septic fever, or from peritonitis with or without intestinal obstruction, *it by no means follows that she will be moved into hospital.* Her condition may be too serious to admit of her being moved, or she may live too far away, and it is therefore quite probable that she may die at home. I would submit that on this account the evidence of the post-mortem room may easily lead to an erroneous conclusion in estimating the mortality of fibroid tumours apart from operation. In the same way, if we seek for the number of patients dying from cancer of the uterus in hospital apart from operation (excluding the Middlesex Hospital, where I believe they are specially allowed to stay till death occurs) we should find that there are practically no deaths from cancer of the uterus, and we might similarly argue that the disease never terminated fatally. In this example we happen to know the reason why such a conclusion would be fallacious—viz., that if nothing can be done by operation to relieve a case of cancer of the uterus, it is not kept in hospital, but goes elsewhere to die. In the case of fibroids we do not know certainly whether there is or is not a fallacy of this kind existing, but the fact that the same line of argument employed in the case of another disease (cancer) leads to a false conclusion should, I think, serve to make us very cautious in accepting the conclusion derived from similar reasoning in the case of fibroid tumours of the uterus. I have myself known one case of uterine fibroid die from hæmorrhage at home—a case that I had promised to take into the hospital, but fatal hæmorrhage occurred before she could be moved.

Fatal cases of ovarian tumour apart from operation are now exceedingly rare, owing, of course, to the fact that cases of ovarian tumour are always operated on nowadays. Fatal cases of ovarian tumour apart from operation therefore hardly ever occur now in the post-mortem room. Here we see again that the evidence of the post-mortem room must not be pressed too far in ascertaining the mortality of a disease. Probably the most serious cases of fibroids are the cases that are most frequently submitted to hysterectomy; thus a whole group comprising the most serious cases is removed from the possibility of figuring in the list of fatal cases of fibroid apart from operation.

I myself fully believe that the mortality of fibroid tumours apart from operation is very low, though the invalidism for which they are responsible is very serious; but it seems to me probable that the mortality is considerably higher than the percentage at which Dr. Champneys has arrived; first, because very probably many cases die at home, and therefore never appear in hospital statistics; secondly, because the cases that would most probably end fatally are the very cases in which hysterectomy is performed; and the subtraction of these cases unduly reduces the number of those classified as fatal cases of fibroid apart from operation.

The second point that seems especially important is the mortality at the present time of abdominal hysterectomy for fibroids. Dr. Champneys' tables of the mortality of this operation collected from five hospitals are most interesting, but to some of us, I venture to think, they will come as a surprise. I am certainly surprised myself to find that in 1896, 1897, and 1898 the mortality of hysterectomy for fibroids at these five hospitals has been 25, 15 5, and 15 9 per cent. Since November, 1896, when I adopted either abdominal pan-hysterectomy from above, or hysterectomy with the intra-peritoneal treatment of the stump according to the method I now follow, I have had 20 consecutive abdominal hysterectomies for uterine fibroids with the loss of only one case, or a mortality of 5 per cent, and there are other gynæcologists whose mortality is as small, or smaller, I believe, even than this

I am, Sirs, yours faithfully,

Harley street, W., Jan. 22nd, 1900. ARTHUR H. N. LEWERS.

To the Editors of THE LANCET.

SIRS,—The excellent address under the above title recently delivered by Dr. Champneys, which appears in THE LANCET of Jan. 20th (p. 147), should afford subject for consideration to all thoughtful surgeons in view of the increasing tendency at the present day towards the routine early treatment of uterine fibro-myomata by abdominal hysterectomy. This treatment in cases of uterine growths too large to admit of vaginal myomectomy was strongly advocated in a paper read before the Obstetrical Society of London in the autumn of 1897.[1] In the discussion which followed it I expressed my dissent from the views held by the author of the paper regarding the duty of recommending early operation in all cases of uterine fibro-myomata—a course rightly adopted in the case of ovarian tumours—on the ground that the two diseases are not comparable as regards the necessity for operative interference, since the great majority of benign uterine growths do not tend to imperil life and may never require surgical interference, while ovarian tumours, on the other hand, usually prove fatal unless removed.

Dr. Champneys, after considering by the light of carefully compiled hospital statistics the probable relative frequency of uterine fibroid disease and enumerating the symptoms to which it may give rise, proceeds to discuss its mortality under two heads: (1) *as apart from any operative interference*; and (2) *after removal of the uterus by abdominal hysterectomy*. He proves conclusively that death *directly* due to the existence of a uterine fibroid growth is an extremely rare occurrence. With this statement I think the profession will generally concur. In my own experience I have met with but one such instance, in the case of an uncomplicated tumour where death was due to heart-failure from sudden uncontrollable hæmorrhage. With regard to the *operative* mortality of uterine fibroids Dr. Champneys's statistics from various hospital records extending over some 10 years past show an average of 17 deaths per 100 operations, or about one in every six patients submitted to hysterectomy. My own total results in this operation, dating from 1882 and including 107 cases treated with the serre-nœud, and 37 by the so-called intra-peritoneal method, show 16 deaths in 144 cases, a mortality of just over 11 per cent. Of these deaths four occurred among my first 10 cases operated on in the early "eighties"; of the 134 abdominal hysterectomies performed since 1886 only 12 have proved fatal, giving a death-rate of 8 9 per cent., which is equal to more than double my average mortality for ovariotomies during the same period.

---

[1] Transactions of the Obstetrical Society of London, vol. xxxix., p. 22.

Feeling as I do with regard to the question of surgical interference with uterine fibroids, I cordially agree with Dr. Champneys's remarks on the ethics of operations At the present day when surgical procedures of every description are multiplying so rapidly and with such gratifying results, I think it our duty to discriminate between operations undertaken for the preservation of life and those now so freely resorted to for the relief of conditions which *do not directly tend to cause death* *In the former case* the risks of a grave operation are counterbalanced by the certain dangers incurred through the disease, and consequently surgical interference, whether it prove successful or not, may be considered as fully justified. But in cases of simple uterine growths, where life is not directly threatened and the disease causes at most but some discomfort without material impairment of health, resort to operation involving a definite risk to life (a possible consequence of any abdominal section) should never be advocated on the ground that a similar procedure has been followed by success in other like instances. That there is a tendency in the profession at the present day to be thus influenced by series of successful operations is, I think, undoubted; and in the discussion at the Obstetrical Society of London above referred to I ventured to point out that the record of 28 hysterectomies with two deaths (a mortality of over 7 per cent) was hardly sufficiently conclusive of the benefits of such treatment to warrant the argument advanced by the writer of the paper in favour of the early removal of uncomplicated myomata of the uterus. My views in this direction receive support from the records of the Chelsea Hospital for Women for the years 1897 and 1898, quoted in Dr. Champneys's address — viz , 73 hysterectomies with nine deaths, a mortality of 12 3 per cent.

In THE LANCET of Jan 13th (p. 99) there appears an abstract of a paper on the "Operative Treatment of Uterine Fibroids" recently read before the Medical Society of London. The author founds his remarks upon 47 cases of abdominal hysterectomy by the intra peritoneal method with only one death, and states that his list includes a series of 39 consecutive recoveries. He concludes his paper with the sanguine observation that the operation of abdominal hysterectomy with intra-peritoneal treatment of the uterine stump may in the future be confidently expected to give a mortality of not more than 1 or 2 per cent. Not having been present at the reading of this paper, I have no definite knowledge of the nature of the cases operated on and can therefore offer no opinion on the results obtained; but unless the majority of the anticipated operations are to be undertaken in cases which from my point of view do not require any surgical interference, I cannot help fearing that the experiences related hardly justify the expectations expressed for the future I had myself some years ago a consecutive series of 20 successful hysterectomies with the serre-nœud, and my last 26 patients treated by this method all made good recoveries. But I have learnt by experience that there is a compensating average in most matters, even in surgical results, and I hesitate to draw deductions as to future mortality rates from any series of successes, however tempting may seem to be the outlook.

In conclusion, I would emphasise what I have said elsewhere on a former occasion—viz., that the successful issue of an operation affords no proof that the procedure in question was essential to the welfare of the patient; and I would further point out that a death resulting from any operation with a recognised mortality rate *if undertaken on insufficient grounds, even though at the special request of the patient*, should be considered by the operator as something worse than a surgical calamity.

I am, Sirs, yours faithfully,

Manchester-square, W, Jan 22nd, 1900 W. A. MEREDITH.

"SHAW v. THE RAILWAY PASSENGERS' ASSURANCE COMPANY."

To the Editors of THE LANCET.

SIRS,—The prominence which your leading article (Jan. 13th) has given to the case of Shaw v the Railway Passengers' Assurance Company induces me to offer a few remarks on the subject. In the first place, I would point out that at the time when the pathological examination was made, now more than a year ago, I knew absolutely nothing about the case or the region from which the specimen had been removed, nor had I been informed that legal proceedings were pending. This will explain why the whole specimen was not preserved, but fortunately for me the microscopical section has been discovered and is now in my possession, and I am willing to submit it for an opinion to any competent morbid histologist (*not a bacteriologist*) in the United Kingdom.

Your article states that the arbitrators had to decide whether the specimen was a blood-clot or a sarcoma. But surely that was not so, for as I was the only person who had examined the specimen microscopically no other witness was in a position to form a reliable opinion. As a matter of fact, the histological appearances were quite characteristic of sarcoma and the specimen presented no difficulty whatever in its recognition. The prolonged cross examination on the possibilities of organising blood-clot, inflammatory tissue, and the like merely served as the proverbial "red herring." The second question submitted to the arbitrators you have thus expressed: "Did the sarcoma exist prior to the accident?" Now, *if the answer had been in the affirmative*, then by the "aggravation" clause in the policy the company would not have been liable, but if in the negative then the company would have insisted on proof that the injury had caused the sarcoma, which in the nature of things would not have been forthcoming. The third question which you have suggested is: "Could the growth have attained the size it did in ten weeks?" The substance removed at the necropsy was considered to weigh about one pound, but in this estimate no allowance is made for the admixture with blood from the incision into the tumour which had been made per rectum nor for the effects of degenerative changes and hæmorrhages in the neoplasm. The possible origin of a sarcoma from blood clot or *inflammatory exudation following* injury is an interesting subject for pathological inquiry but did not bear on the question which the arbitrators were appointed to decide; and it must be remembered that the injury was received in the left loin—while the sarcoma developed deeply within the cavity of the true pelvis A side issue raised at the trial and made much of by the opposing counsel had reference to the alleged date on which the parcel was received at the laboratory. However, the date of delivery as recorded by the railway company and the date of its receipt as entered at the laboratory are the same (on Monday morning), and it was merely an impression of mine which I had no means of verifying that the parcel arrived late on the previous Saturday evening. The parcel was distinctly labeled with the sender's name and was numbered in the usual manner at the laboratory, so that confusion was quite impossible. Two facts remain. Mr. Shaw received an injury to the loin on Sept 15th; he died on Nov. 24th from a sarcoma in the pelvis which had obstructed the bowels and urinary passages. The proximate cause of death was disease, and therefore by the terms of the policy the company was unquestionably entitled to the finding of the court.

I am, Sirs, yours faithfully,

St Thomas's street, Jan. 23rd, 1900. J H TARGETT.

"OPERATIONS FOR ACUTE APPENDICITIS."

To the Editors of THE LANCET.

SIRS,—Mr. Berry asks me two questions: (1) at what stage do I operate? and (2) which cases should be operated on without regard to adhesions? Unless the attack is a mild one or apparently passing off, or in a stage at which intervention would be hopeless, I now operate at once. I used to follow Mr. Berry's practice of "waiting for a few days until adhesions to the anterior abdominal wall have formed and then making an incision into the abscess through the area of adherent peritoneum." I found this occasionally meant waiting too long and then devised the operation described in THE LANCET of Jan. 13th. I am surprised that Mr. Berry sees no essential difference between this and the older plan. Perhaps my diagram (Fig. 1, p. 87) may have misled him. It does not, and is not meant to, indicate steps "6" and "7" of the operation (see p. 88). My operation bears the same relation to the usual one that a flank attack does to a frontal one. It ends in opening the abscess cavity in the manner described as "steps 6 and 7." It therefore perforates the peritoneum but does not open the general peritoneal cavity. This operation is indicated when a fixed tumour can be felt in the iliac fossa When such a tumour is deep and the abdomen tense it may not be discovered until anæsthesia has been obtained. When there is a moveable tumour I open the general peritoneal cavity, afterwards proceeding in the manner described in the latter half of the last paragraph but three on p. 88. The variety of cases of appendicitis is so great that since the publication of that paragraph I have been reminded of one not provided for in it—viz, the case in which "the appendix, in spite of inflammatory thickening, floats free in the peritoneal cavity," while the latter *does* show signs of general infection. Mr. Bott, Dr. Dixson, and I have just had in the Brentford Cottage Hospital a very severe case of this kind. We removed the appendix, dealt with the general peritonitis, chiefly by careful swabbing, and the patient, a boy, aged 14 years, is convalescent. The symptoms had commenced 60 hours before operation. 24 hours more might have been fatal; 24 hours less would, I cannot help thinking, have been safer.

I believe in the proper use of statistics, but they are not required to prove the desirability of saving some of the cases which are now lost under, if not through, a policy of delay. My conversion to these views has been gradual, my putting them into practice recent. Appendicitis is so fatal as it is because it is not nearly so fatal as it might be, and further because so many people base upon a limited personal experience a belief that appendicitis is less fatal, less injurious to health, and less wasteful of time than it really is; and so surgery is kept at a distance as a thing known to be disagreeable and hoped to be unnecessary.

At the risk of being misunderstood, but from a feeling of duty, I will add a warning which I believe Mr. Berry will endorse. Intra-peritoneal operation on the diseased appendix requires a combination of experience with some natural capacity. Every case has its individual peculiarities, some of which may require resource and nerve. The qualities demanded are not to be got by a course of operative surgery on the dead subject even when combined with a course of practical bacteriology.

I am, Sirs, yours faithfully,
Grosvenor street, W., Jan. 22nd, 1900. C. B. KEETLEY.

"A CASE OF SUPRAPUBIC LITHOTOMY; REMOVAL OF TWO VESICAL CALCULI; RECOVERY."

To the Editors of THE LANCET.

SIRS,—Permit me to thank Dr. W. A. Mackay for the polite language he has used towards me in commenting upon my recent case of suprapubic lithotomy in a young child. I do not quite admit that Dr. Mackay is right in his statement "that the suprapubic operation has proved itself in childhood of all methods the most fatal." Statistics are not everything. Outside the employment of lithotrity in suitable cases no one can be a stronger advocate than myself for lateral lithotomy, but I still adhere to my assertion that in young male children it is not an easy operation, for be it remembered the line of procedure is through structure so diminutive and the space for working so narrow that unless the surgeon uses the utmost care he may possibly come to grief. I have operated by perineal lithotomy upon quite 300 cases of stone in the bladder, of all ages, and, of course, I have lithotrised many as well, so that if I have a bias it would be for lateral lithotomy; but my reason for selecting the high operation in the case reported was that I suspected the stone or stones were not free in the bladder (as was proved), and I know from experience how difficult it often is to remove by the lateral perineal method a stone or stones which are pouched or partly so. I am in accord with Dr. Mackay's opinion that suprapubic lithotomy must not be considered in young male children a routine operation; indeed, it ought to be resorted to as an exceptional operation in exceptional cases.

I am, Sirs, yours faithfully,
Wolverhampton, Jan 23rd, 1900. T. VINCENT JACKSON.

THE INFLUENCE OF WEATHER ON VACCINE LYMPH.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of Dec. 30th, 1899, in the *Annus Medicus*, page 1833, col. 1, lines 2 to 15, and at page 1839, in the last 10 lines of the article on "Vaccination in 1899," you treat of the lack of activity of vaccine lymph during hot weather. You mention that you have set an inquiry on foot the results of which will be published shortly. You also say that the difficulty has been met in some countries by suspending vaccination during hot weather and that the remedy will doubtless be found to lie in the preparation of the lymph during the cold weather to be stored for use during the hot months.

Recently Dr. Loir of Tunis supplied a communication to the Academy of Medicine wherein he sought to establish the fact that vaccination should not be performed in hot countries from June to November.[1] Dr. Hervieux, the chief of the vaccination department of the Academy of Medicine, is strongly opposed to this view, as, indeed, I am myself, and as a matter of fact I am writing a paper on this point which Dr. Hervieux will on my behalf lay before the Academy. It occurred to me that as you are making inquiries upon the matter we might help one another: I could assist your inquiry by furnishing you with the details of my work now in progress and you could help me by furnishing me with the results of your inquiry.

At this moment I am able to affirm that if hot weather has any evil influence upon the activity of vaccine lymph this can be met and conquered up to a certain point. The cause, however, of the want of activity in vaccine lymph should be sought for elsewhere than in hot weather. Two matters are more important than the heat of the weather—(1) the influence of the calf and (2) the influence of the inoculating lymph (*semence*). The importance of the rôle played by the calf is obvious from a consideration of the following facts. Let two calves be vaccinated on the same day, at the same time, under the same conditions, and with the same lymph. One of these calves will give excellent vaccine lymph while the other will produce a lymph which is very defective in vaccinal quality. The importance of the rôle played by the lymph is shown as follows. At one vaccine station they had a whole series of defective crops (*récoltes*); several calves were vaccinated, some with the ordinary lymph of the establishment, others with lymph coming from another station. The former lot gave very indifferent lymph, the latter excellent; but what demonstrates anew the influence of the *calf* or of its *surroundings* is the fact that other calves vaccinated with the good lymph collected in this station and originating from lymph sent from the other station gave, after the lymph had passed through some three calves, defective lymph.

Hot weather goes for nothing as regards the failure of the lymph observed during 1899, for (1) failures were not observed everywhere and some stations had excellent crops all the year through; and (2) deficiency in quality was noted in the cold weather as well as in the hot. In one station with which I am personally acquainted there were throughout the year *only two defective* crops, the one collected on March 13th, the other on July 17th. All the other crops, including those of June, July, and September were of excellent quality. There was no August crop on account of the director of the institute being away and provision was made in July for a supply for August. At the same station during another year there were 20 crops which failed and they were nearly all collected between April and May. At another station which I know, presided over by a bacteriologist who is as well known in England as in France, some two years ago the crops collected in the spring were defective while those collected in the summer were of excellent quality. For these latter results all the calves had been vaccinated with a lymph of exceptionally high power coming from another station.

---

[1] THE LANCET, Nov. 4th, 1899, p. 1265.

In the English colony of Natal vaccinations are performed at any time of the year with lymph sent from Europe. I know that during the hot weather a year ago the results were excellent and I should have been informed if the results were not the same in 1899.

It is proposed to store lymph for use in hot weather which has been collected during cold weather. I have lately made some experiments with vaccine lymph collected in April the efficacy of which was perfect at the moment of collection. Here are my results at the end of three days:—

With *Vaccine No. 9*, collected on April 10th, two children were inoculated, two insertions being made in each child. The insertions were made in these and in the following cases by superficial incisions of about one centimetre in length. In the first child there developed from one incision *three* small vesicles. They were badly developed and discrete the one from the other. From the other incision only *two* small vesicles developed. In the second child there were *two* vesicles of the same length as the respective incisions, but with very irregular edges.

With *Vaccine No. 12*, collected on April 17th, two children were inoculated. In the first child there developed from one incision *two* small vesicles. They were badly developed, and discrete the one from another. From the other incision only *one* small vesicle badly developed. In the second child there were *two* vesicles of the same length as the respective incisions, but with very irregular edges.

With *Vaccine No 13*, collected on April 17th, two children were inoculated. In each child there developed *two* vesicles of the same length as the respective incisions, but with irregular edges.

With *Vaccine No 14*, collected on April 17th, two children were inoculated. In the first child there developed from one incision *one* small vesicle. The other incision gave no result whatever. In the second child there developed from each incision *one* vesicle only They were small and badly developed.

With *Vaccine No. 15*, collected on April 24th, one child was inoculated. From one incision there developed *three* small and badly-developed vesicles. From the other incision nothing developed.

With *Vaccine No. 17*, collected on April 24th, one child was inoculated. Each incision developed a vesicle of corresponding length but with irregular edges.

It is to be noted that when the lymph is very active it produces regularly-shaped pustules as long as the insertion incisions. The following is the table for revaccinations:—

Vaccine.	Successes.	Number vaccinated.	Percentage.
No. 9	3	24	12 50
,, 14	3	20	15 00
,, 28 (of June 19th)	25	165	15·15

These last results are altogether bad and show that old vaccine lymph should never be employed, especially for revaccinations. Again, for primary vaccinations the vaccines which I have employed in my experiments should have already proved inefficacious in the hands of many vaccinators if used in public vaccinations.

I am Sirs, yours faithfully,
DR. EDMOND CHAUMIER.

Tours, Jan 1st, 1900.

THE TREATMENT OF PANNUS BY JEQUIRITY.

To the Editors of THE LANCET.

SIRS,—I have read with much interest your admirable review of the "System of Diseases of the Eye," by American, &c., authors, but I cannot allow to pass without a strong protest the unfavourable opinion therein expressed in regard to the treatment of pannus by means of jequirity. I have frequently used this remedy and have seen it used by other surgeons with marked success where all other lines of treatment had failed.

I am, Sirs, yours faithfully,
ROBERT J. MONTGOMERY, F.R.C.S. Irel.,
Assistant Surgeon, Royal Victoria Eye and Ear Hospital, Dublin.

Dublin, January, 1900.

TO THE THIRD GENERATION: THE CONTAGIOUSNESS OF INHERITED SYPHILIS;

THE DISTURBANCE OF LATENCY IN SYPHILIS UNDER THE INFLUENCE OF CONCEPTION IN THE WOMAN; INHERITED MATERNAL TRANSMISSION.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 25th, 1899, a case of possible syphilitic inheritance in the third generation observed by Mr. Hutchinson is noted, and in THE LANCET of Dec. 9th the contagiousness of inherited syphilis in the second generation is affirmed by Dr. L. Kolipinski. Mr. Nunn has recorded a possible case combining both these propositions.

> In this sequence the grandmother had originally acquired syphilis from her husband The daughter, who herself showed evidence of past inherited disease, gave birth to a syphilitic infant, who re infected the grandmother with digital chancre followed by secondary signs In the father of this infant after the most critical examination there was no reasonable suspicion or history that he had ever suffered from venereal disease "Unless," remarked Mr Nunn, "there lurk some defect in the evidence, here were three generations syphilitic from the same source[1]

Some little time ago I ventured to suggest that the actual condition of the woman previous to, or on, conception—apart from those pathognomonic symptoms of past inherited disease pointed out by Mr. Hutchinson—afforded room for the supposition of full or partial inherited maternal transmission to the third generation; and I should be much obliged if I might submit this aspect of this question in view of the statement in THE LANCET of Nov 25th, that "Nothing was *a priori* more improbable than that hereditary taint should survive to the third generation." This conclusion, together with the view of probable acquisition in all cases, is apparently founded more immediately upon the known acquisition of disease by the father previously to marriage in one of Mr. Hutchinson's cases, upon the possibility of acquired paternal transmission to the child in the case which forms the subject of your annotation, and upon the rarity of possible cases. Admitting these, together with the possibility of acquired disease in the woman previously to marriage, the hypothesis of paternal transmission to an infant by a "third party" other than the legal father, and the possible diminution of inherited syphilis in the second generation itself, I submit that this *a priori* belief in probable acquisition is weakened by the fact that no reference is made to the absence of suspicion in the husband recorded by observers in other cases, to the possible cases of active inherited manifestations previously to or on conception in the woman, or to the disturbance of latency with manifestations under the influence of conception known to occur in the woman in subsequent pregnancies after previously acquired disease and noted as such in the possible subject of inherited syphilis. Furthermore, I venture to think that insufficient allowance is made for the difficulties attending inquiry into possible cases of this kind in private and hospital practice, or publication of details, as well as for the assumption of paternal acquisition and transmission, in the general absence of inquiry into or suspicion of the previous or parental history of the mother herself in cases which excite suspicion of venereal disease in her or her offspring. "To be as conclusive as possible" in the diagnosis of tardy inherited symptoms in the adult as opposed to acquisition one of the conditions formulated by Diday was that "it must be lastly known whether the parents (of the subject) at the moment of fecundation were in a condition to transmit syphilis."[2] It is this condition of the woman at the time of conception and ability of herself to transmit which seems to me to be of some importance in the question of transmission to the third generation.

Diday goes on to note that "Bell teaches positively that hereditary syphilis may remain latent in the child until the period of puberty or in the adolescent until the time of marriage or of confinement, circumstances which he regards as a sort of crisis capable of inducing the appearance of these symptoms." I have not so far been able to find this reference for myself, but the appearance or re-appearance of symptoms at puberty have been recognised and catarrhal affections of the genital and other mucous tracts noted. With respect to the same in the adult, the objections to which such cases are liable are obvious, especially as regards genital mucous affections; and yet amongst the numerous cases originally recorded[3] of leucorrhœas, uterine erosions, menorrhagias in young unmarried women under the heading of "struma," it is almost impossible to doubt that some were unrecognised cases of inherited syphilis; more especially as under the "scrofulous diathesis affections of the eyes leaving interstitial deposition between the layers of the cornea" were noted.[4]

---

[1] British Gynæcological Journal, [illegible]

The subsequent histories in these cases are aggravation of symptoms on marriage with sterility; or on conception, muco-purulent or purulent discharge through pregnancy, repeated abortions, or premature births, and subsequent pronounced uterine inflammatory disease. With regard to offspring, there is but little noted in these treatises especially devoted to the diseases of women and there is only the note of offspring who either did not survive long or were healthy and the expression of belief in transmission of syphilis to the third and fourth generation in obvious form, or, amongst other causes, in the inherited syphilitic origin of "struma." Attention, however, appears to have been directed to the state of the husband in cases simulating acquired venereal disease, and in some of these cases he was as far as possible exculpated from blame. In some suspected cases of this group which have come under my own limited observation, well-marked notched central upper incisors have been present in the woman, or these teeth have been entirely absent (Dr. Laycock, quoted by Dr. J. G. Beaney, stated that the characteristic groove is "usually obliterated by the twentieth year"); in other cases disease in the parent of the woman has been volunteered, and in a few cases I do not think there has been any reason to suspect the husband of past or present syphilis or gonorrhœa.

Whitehead recorded a possible case of general, genital and uterine manifestations in a young married woman.[5]

> In this case he on inquiry traced a succession of symptoms from infancy, through childhood to adult age, marriage, and possible conception, and regarded them as due to syphilitic inheritance. His suspicions of syphilitic taint being raised he asked for an interview with the husband, but instead the mother of the young woman came and acknowledged to disease in herself and second husband previously to the birth of the daughter.

At what time, however, the grandmother became contaminated by a first or second husband is open to doubt. Less objection can, perhaps, be taken to a case of Gilbert's quoted by Diday in favour of tardy inherited syphilis in the adult woman under the disturbing influence of conception:—

> It is that of a young woman of bad constitution, who, after the birth of one infant who wasted rapidly and died on the seventeenth day, and of another healthy at the age of two, herself exhibited swellings, one of which, over the clavicle, suppurated and ulcerated. A node also was noted on the tibia. In this case there was reported syphilis in the parents of the woman, but no evidence or history of acquisition in herself or her husband.

This group of possible cases, I admit, favours symptoms in the mother with abortions and premature births rather than actual transmission to the third generation. The possible case, however, adduced by Mr. (afterwards Sir John) Simon, and referred to by Mr. Nunn bears more directly.

> The woman, whose father had died of tertiary syphilis, herself had a first child who was judged to be syphilitic, and had in her own person some symptoms which were ascribed to the same poison, there being not the smallest possibility of syphilis as far as could be ascertained coming to her in any way otherwise than that of descent.[6]

After previously acquired disease in the woman it is known that manifestations may re-appear in subsequent pregnancies in the form of syphilides, genital and uterine lesions, purulent discharge, abortions, premature births, full or partial transmission to offspring, with subsequent fever and confirmed inflammatory uterine and pelvic disease in the mother (or death of the mother in childbed, as noted from septicæmia in one of Dr. Kolipinski's cases in THE LANCET of Dec. 9th) "Facts of this kind are numerous, and to be convinced of this it is only necessary to read the observations furnished by authors."[7] Moreover, cases have been noted of syphilis in the offspring of women previously diseased by a first and married to a second, even third, healthy husband, the woman herself apparently remaining healthy or exhibiting only uterine disease.[8]

From such facts as these it is difficult to believe that the same disturbance of latency and transmission to offspring may not occur in the case of inherited syphilis; that if symptoms are present in the mother they may not be due to revival of disease in herself rather than re-infection; and that there is no survival of hereditary taint in some at least of her offspring. The same argument, of course, applies to cases in which the woman has acquired disease previously to marriage. The question also of acquisition in infancy cannot be ignored, with subsequent symptoms in adult life. In Whitehead's case previously referred to, and possibly in Diday's, Simon's, and in unsuspected others, there may have been acquired syphilis in infancy or childhood, with re-appearance in the innocent woman of manifestations on conception, or maternal transmission. Whitehead records a definite case of lip infection in a girl of 11 years of age with subsequent constant leucorrhœa, vaginal irritation, and other symptoms, who ten years later gave birth to a syphilitic infant followed in the mother by uterine inflammatory disease, while the husband in this case had "never suffered from syphilis in any shape."[9]

I am, Sirs, yours faithfully,

JOHN A. SHAW-MACKENZIE.

Grosvenor street, W., Jan. 22nd, 1900.

"THE UNIVERSITY OF LONDON ELECTION: THE CANDIDATURE OF DR. W. J. COLLINS."

To the Editors of THE LANCET.

SIRS,—The anonymous letter which appeared in THE LANCET of Jan. 13th under the above heading contains at least one mis-statement of fact, but it breathes such a tone of virulent opposition as to render a reply hardly necessary. I rely, however, on your well-known love of fair play to permit me to add a word or two to the comments contained in your annotation on the same subject in which you say (p. 117) that Dr Collins is "at variance with accepted scientific belief on the question of vaccination." As one of the Royal Commissioners appointed by Her Majesty to inquire into the subject of vaccination Dr. Collins has had exceptional opportunities for studying the subject and has given us his views at considerable length in what is known as the "Dissentients' Report," signed by Mr. Picton and himself. It would occupy too much space to quote from this at sufficient length, but I cannot do better than refer to the leading article in THE LANCET of Oct. 31st, 1896, p. 1241. In dealing with that report you adopt the following as a summary of the views held by these gentlemen:—

> One thing is certain from a perusal of the very guarded terms in which the dissentient Commissioners refer to vaccination, and that is that they believe vaccination to be a means of protection against small-pox. Nowhere, as we point out in another column, do they express a disbelief in vaccination as a power against small-pox. Indeed, they go far beyond giving this negative testimony of their faith in vaccination They assert in a positive form that it is both an "effective and trustworthy prophylactic" because they propound the question in a *comparative* form as to whether vaccination can be regarded as a "more" effective and trustworthy agent in the control of small-pox than sanitation and isolation. Then, again, they really advocate vaccination, for they actually suggest that "moral influence" may properly be used in pressing it upon the population, and this attitude pretty well disposes of their having any belief in the terrible risks which, according to some people, are involved in the operation. With some of the recommendations of the dissentients it is obvious that everyone will agree

It is possible that Dr. Collins may not be "an embodied expression of the highest medical opinion," though I personally should not be inclined to admit even this without discussion, in view of his vast knowledge of this and other subjects, and the distinguished position he has taken at our university examinations. But I do not think anyone after a careful perusal of the report in question and the valuable criticism of THE LANCET thereon can maintain that Dr. Collins is at variance on any important or vital point with the accepted scientific belief on the question of vaccination. Indeed, he has won the cordial support of hundreds of his fellow graduates, including a large number of medical and surgical alumni of the University of London, who believe he would be as useful in Parliament as he has been in the London County Council.

PROPOSED PUBLIC MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I am glad to see that Mr. M. J. Houghton is developing the above proposal. In the *British Medical Journal* of June 22nd, 1889, I suggested the formation of such a service. At first I suggested that it should contain only one department which I termed the "*cash fee department.*" But Dr. H. Woods pointed out to me that it should contain also a department by which persons in health could insure for treatment when ill. I agreed to recommend a provident department also. I think two or three such public medical services exist—one in Coventry and one in Hartlepool. They have not, I understand, adhered to all my suggested rules. *At present I would not advise that this name be continued* and I would suggest that in place of it the term "Provident Medical Service" be adopted

My aim in suggesting such a service was to show that, from long back, practitioners should not have left it to *non-medical persons* to establish sick-clubs of any kind whatsoever. I took up this position—that the wage-paid classes *have no more right to employ me as their medical servant* in a sick-club capacity than I have to interfere with (or exploit) the grocer, &c., who kindly sells to me groceries, &c. Let *all* practitioners agree *not* to act as medical officers to *all* sick-clubs; let the sick-clubs carry on their chief functions as related to sick pay, funeral allowance, &c.; let a provident medical association be established in each town, with branches if necessary, and then touting for clubs, the medical aid association nuisance, hospital abuse, and kindred subjects will disappear. The question of hospital abuse can never become a practical question until such a service is in thorough working order, as it would be cruelty for a hospital committee to refuse treatment unless they could refer the applicant to such a trusted service. My only fear is that such a service would run a great danger of being ruined by not having a rigid "wage limit" for membership, and thus hospital abuse if corrected at the hospital would not be cured but only transferred to the service. Doctors are a *most unbusinesslike class*

I am, Sirs, yours faithfully,
Liverpool ROBERT R. RENTOUL.

MOSQUITOS AND MALARIA.

To the Editors of THE LANCET.

SIRS,—Permit me to call attention to a slight error that is expressed in your columns[1] in regard to the discovery of the anopheles as a carrier or host of the quartan malarial parasite. It is stated that "within a short time of his arrival at Sierra Leone Major Ross was able to telegraph that he had found the malarial organisms within the bodies of the anopheles and further that he had proved that the insects would also act as carriers of the quartan parasite." As Grassi, Bignami, and Bastianelli[2] published on Feb. 5th, 1899, that they had succeeded in experimentally infecting anopheles claviger with quartan parasites by feeding it on a woman suffering from a severe quartan infection and that they had found stages of development of the organism in the stomach wall of the mosquito so infected, it is clear that the credit of the discovery is due to them and not to Ross. I have been influenced to call attention to this fact for the reason that on several previous occasions the same error has found expression in the columns of THE LANCET and of other medical journals.

I am, Sirs, yours faithfully,
IRVING P. LYON.

Buffalo, N.Y., U.S.A., Jan 14th, 1900.

*** The claim which Dr. Lyon contradicts does not seem to us to be made in the words which he quotes.—ED. L.

"THE MURMURS OF MITRAL STENOSIS."

To the Editors of THE LANCET.

SIRS,—Dr. Sansom in your issue of Jan. 20th (p. 195) has protested against the statement in my letter of a fortnight previously that his article in Professor Allbutt's "System of Medicine" misrepresents me. I did not mean that his *résumé* of my views was inaccurate, but rather that it was calculated to leave an inaccurate impression. Dr. Sansom's quotations from my Paris thesis of 1896 show that I am largely responsible for this, since auricular hypertrophy, on which I there lay so much stress, implies an extra ("abnormal") powerful contraction of the auricle. In the thesis I magnified the importance of hypertrophy as the most tangible part of the evidence of the possibilities of the auricle. This was out of consideration for the probable training and prejudices of the examiners for whom it was prepared. I imagined that if I could get them to admit the probability of my theory when the auricle was hypertrophied I might then lead them a step further—viz., to recognise that it was also possible, at least theoretically, when the auricle was not hypertrophied. The thesis was well received as I gained a "très bien" for it and was asked to write a *résumé* for the "Archives de Médecine Expérimentale et d'Anatomie Pathologique," which I did.

A few pages beyond Dr. Sansom's second quotation from my thesis—viz., on page 41—I venture to state why I gave such prominence to the element of hypertrophy: "Pour satisfaire ceux qui croient plus à la force musculaire qu'aux principes mécaniques, j'attire encore une fois leur attention sur ce fait que j'ai toujours supposé une oreillette hypertrophiée et non dilatée." But I continued, p. 42: "Mais, même s'il n'y avait pas d'hypertrophie de l'oreillette (et je ne suppose pas que l'hypertrophie existe pour lui donner la faculté de résister au ventricule, ce à quoi il a été, j'imagine, toujours plus ou moins habitué, mais pour lui donner le pouvoir de pousser le sang avec une vitesse suffisante au travers d'un orifice rétréci), il serait mécaniquement vrai qu'un ventricule vigoureux, lorsqu'il est gros, ne peut pas dilater une oreillette faible quand elle est suffisament petite, pas plus qu'un gros ballon, distendu, fait en caoutchouc épais, ne peut dilater un petit ballon, distendu, et fait en caoutchouc mince, lorsqu'il est mis en communication avec ce dernier." It is clear, therefore, that even in my Paris thesis, my earliest publication on the subject, I did not regard a hypertrophy of the auricle as essential though I have always maintained it to be helpful; still that thesis, written against time as it was, has given undue importance to the valuable element of hypertrophy and justified Dr. Sansom's term "abnormally powerful" far more than my somewhat offensive expression "misrepresents me," which I very much regret having employed, and trust Dr. Sansom will add another to my many debts of gratitude to him by accepting my sincere apology.

The term "abnormal" evidently conveys a different impression to different minds. Thus in answer to my question "Is it abnormal that the smaller piston of a Bramah press should be able to force up the larger?" Dr. Brockbank replies "yes," where I should have said "no." His words are: "Yes, *it is impossible for the smaller piston* to press up the larger unless it be plunged with sufficient force to overcome the resistance of the large piston." Surely that is a normal and not an abnormal physical fact—a fact in hydrostatics which indicates that given suitable mechanical conditions a very weak force can overcome a very great resistance. Such a mechanical advantage the auricle has when it has nearly emptied itself and presents a small internal area to oppose a full ventricle beginning to contract and presenting a large internal area, for this is their relative condition *as regards area* when their contractions overlap.

Dr. Brockbank cannot get away from the idea of a considerable force to produce considerable pressure. If he will get a multiplying pulley gear and put a small child to pull the rope while he holds the free pulley, he will discover that the child can easily pull him over, but he must not conclude therefrom that the [illegible] exerts a man's force Si[illegible]
er, the re

[2] Reale Accademia dei Lincei, vol. viii., 5 febbraio, 1899.

to, he will readily understand that mechanical advantage may allow great blood-pressure to be generated by forces quite insufficient to produce it without that advantage. Dr. Brockbank says: "It is impossible for an auricle to hold up the ventricle and prevent the regurgitation of blood, which I believe creates a crescendo murmur, unless the auricle contract with sufficient force to do this. That an auricle possesses such power at any time, especially in mitral stenosis when it is so often abnormally thin, has not been proved, nor is it probable that it does possess such power." Is the auricle "so often abnormally *thin*" in mitral stenosis? Even in the post-mortem room, where all the effects of the heart's final failures and breakdown are especially displayed, I have shown that 44 out of 77 cases of severe mitral stenosis at Guy's Hospital are recorded as having the auricle hypertrophied, and hypertrophied in nearly one-fourth of the slight cases, while in cases of stenosis dying in the surgical wards of something else auricular dilatation is strikingly rare, and if I remember correctly the auricle was never sufficiently thin for it to be remarked.

Nothing in medicine is of universal application and no theory can be demonstrated by every case. I am quite prepared to admit that when an auricle is abnormally thin it is abnormally weak and may fail to defend a stenosed mitral orifice, even as it may fail to produce an auricular-systolic murmur. Such failure affects no principle of action.

Moreover, it is exceedingly "probable" that the auricle does possess the power Dr. Brockbank denies to it. The auricles have even been known, as in a case of ventricular calcification, to bear the whole brunt of the circulation and maintain it. So far as the mechanics of the circulation are concerned the heart is a mechanical instrument subject to mechanical laws, and one is (1) that the thickness of a contracting sphere varies inversely as the square of its diameter; and the pressure it can exert on its contents, if the contraction of its fibres be constant in force, is proportional to the wall thickness. If this is not understandable it may be put thus: with the same number of contracting muscular fibres the surface of blood to be pressed on varies directly as the square of the diameter and is therefore, or may be, subjected to a pressure varying inversely as the square. Another law is, (2) the pressure a contracting sphere can exert on its contents varies inversely as the diameter of the sphere. This latter depends not on the wall thickness but on the increased curve of the decreasing sphere (*vice versâ*) which makes its contractions more effective on its contents when small. So, if an auricle in contracting become a sphere of one third its initial diameter it can theoretically exert a pressure of 27 times its original amount. If it did but half this it would be sufficient for the purpose of my theory. This is neglecting hypertrophy, which is often present in slight and usually present in severe cases of stenosis, and which is always a reserve factor in my favour. The effect of the escape of the liquor amnii in augmenting the pressure of the uterus on the fœtus is due to the operation of the same two laws, for size is indirectly more a pressure factor than is muscle. The ventricle differs from the auricle in having from the beginning and when large to expel its blood against high pressure. If its load came on it at the end when the ventricle has become small, as the auricle's does, its walls might be several times thinner than they are.

Dr. Sansom points out very opportunely and with great reason in his letter that if regurgitation be a feature of mitral stenosis, as Dr. Brockbank's theory demands, "there would in all probability have ensued dilatation of the cavity of the ventricle, for mitral regurgitation in any notable degree is followed by enlargement of the ventricular cavity. As this cavity is observed to be small it is a fair inference that regurgitation has been prevented by some change making for compensation." For my reply to Dr. Woods's third objection which Dr. Brockbank quotes I must refer him to my letter in the *British Medical Journal* of March 20th, 1897, p. 767.

There are many other matters of interest in Dr. Brockbank's and Dr. Theodore Fisher's letters which some day we may better agree over, especially if I learn meanwhile from Dr. Sansom's just rebuke to be a little more courteous in my criticisms.

I am, Sirs, yours faithfully,

D. W. SAMWAYS.

Mentone, Jan. 22nd, 1900.

PUBLIC HEALTH OF DUBLIN:

THE RE-HOUSING OF THE POOR.—THE BACTERIA IN THE SOIL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from Jan 20th, p. 201.)

ON the south side of the Liffey, behind and not far from Dublin Castle, there is a broad thoroughfare called Peter-street. In former times this street was evidently inhabited by wealthy people, but it has quite fallen from its high estate. A part of the street is now occupied by the Adelaide Hospital, and such is the poverty-stricken condition of the surroundings, that the house next door to the hospital is in ruins and uninhabited. It should be easy to purchase this house and utilise the site to enlarge the hospital. On the opposite side of the street there is a whole row of tenement houses which have been handsome private dwellings, five storeys high, but the first one I entered I found to be inhabited by no less than 15 different families. For this numerous population there is but one closet situated in the back-yard, which is below the street level. As no one is responsible for this closet and charged with keeping it in order it has been broken to pieces; there is filth on all sides and the place is absolutely unfit for use. Next door and for a similar house there is also only one closet in the back-yard, and here the water-supply pipe is out of order. The water flows continuously over the closet-seat; it does not enter the pan, but forms quite a little rivulet in the middle of the yard. This is a great waste of water, for it does not even serve to flush the soil-pipe. These closets need to be rebuilt. Inside the houses there were the usual evidences of neglect and poverty—cobwebs on the stairs and dust and dirt on all sides; the interior of the rooms varying according to the character of the tenants.

Throughout Dublin, and constituting a special feature of the city, it is impossible not to be sadly impressed by the great number of abandoned, uninhabited, and dilapidated houses that are rapidly falling into ruins. But in going from Peter-street to the Coombe district I came across a greater number of these houses than usual. In some cases the roof has entirely disappeared. I noticed three such houses in Coombe-street. Others have one or two inside floors broken in as if the shell of a 100 ton gun had passed through them. Park-street, off Ash-street, presented a veritable scene of desolation. There were great gaps where houses had formerly stood—even the outer walls had given way. Other houses, still standing, had no window-frames remaining, and from a lower window it was sometimes possible to see to the top of the inside of the house, because the intervening floors had all gone. Ash-street is, indeed, a lugubrious and sinister thoroughfare. It cannot boast even of a gutter, and not many paving-stones remain. In the centre of the street there is an irregular indentation which serves as a sort of surface drain. The closets in the yards behind the houses are indescribably filthy. Fæcal matter is strewn in all directions, and close to this foulness people sleep, on the ground floor and on beds that have no bedclothes. The weary lie down without undressing and with the dirt of the neighbourhood clinging to them. Then there is the terrible aspect of the inhabitants, especially the women, whose sordid, torn, greasy, and ragged clothes hardly hang on them. At the corner of Vicar-street notably there is a house that is falling to pieces, and it seems extraordinary that there should be so much property in the heart of the town, and not far from the Castle, that is thus tenantless and in ruins. Here and there, it is true, some poor people crawl in and inhabit a room or two in a house which has partially lost its roof and the greater part of its windows. Doubtless they have no business to be there and perhaps pay no rent, but in the midst of such poverty, recklessness, and neglect the wretched sufferers resort to every expedient. The authorities can close a house as unfit for habitation (as a matter of fact some 1500 houses in Dublin have thus been closed) and as no compensation is given this is the easiest manner of dealing with insanitary property. A scheme for rebuilding such houses under the Housing of the Working Classes Act would be an expensive and complicated matter; and though a good deal is being done under this Act all the unhealthy houses and all the bad property cannot at one and the same time be treated in this manner. On the other hand, many of the owners of these wretched dwellings are very poor and cannot afford to put their property in proper repair, so the houses are closed and fall into ruins.

In Smith-alley I came across another public fountain, similar to the one situated in Taafe court already described. Here, again, there was fæcal matter round the tap, and people were emptying the soil from their pails on the gully under the tap where others came to fetch their supply of drinking water. At this spot a girl about 12 years of age came past. On one foot she wore a man's boot; the other foot was bare. She had nothing on her head and very little on her body, and it was a cold winter morning. The poverty that this sorrowful sight indicated is such that many of the poor strive to rent a room for 8*d.* per week. Of course, no suitable room can be obtained for this price, but there are a few noisome back basements that are let out for that sum. Many of the persons who lodge in such places have no better occupation than that of going long distances in the early morning so as to pick up cockles in the Bay of Dublin. These they sell at night at the street-corners. When this class of people succeed in paying 1*s.* a week rent they consider it quite an achievement and flatter themselves that they have already risen in social rank. This is where the difficulty of municipal action comes in. It is comparatively easy to provide model dwellings that will be readily rented at such rents as will prove remunerative, but this class of people cannot be the tenants. After all this it was a very pleasing sight to visit some of the newly constructed quarters, such as the Thomas Davis district and notably John Dillon street. Here there are small neat red-brick cottages. Each tenant has his own closet and can therefore keep it clean, in good repair, and in working order. In front of the houses the road is asphalted. Consequently it is comparatively free from dirt or mud, there is less damp, and the subsoil cannot be contaminated.

In Blackhall-place there are 15 self-contained houses at 7*s.* 6*d.* per week, five shops at 6*s.* 6*d.*, five two-roomed dwellings at 3*s.* 6*d.*, 14 at 4*s.*, 14 at 3*s.* 9*d.*, 14 at 3*s.* 3*d.*, and 14 at 3*s.* On visiting one of these tenements for which 3*s.* 9*d.* is charged I found that, though the appointments were all good, the second room, used as a bedroom, seemed to be very small. Seeing what is done in London, where the ground-rent is much higher, the rent charged appears excessive. In the Bow-lane district there are 86 model tenements. Five of them have shops and are rented at 5*s.* to 5*s.* 6*d.*, the rent for the others varies from 2*s.* to 4*s.* 6*d.*, the latter having three rooms. There are 19 two roomed tenements at 2*s.* In the Benburb street district there are 23 one-roomed tenements at 1*s.* 6*d.*, 14 at 1*s.* 9*d.*, and 28 at 2*s.*, and 76 tenements at higher rents. From the sanitary point of view it is the cheapest of these tenements that are of the greatest use and interest.

Of course it is the extreme poor who are the most difficult to deal with. Fortunately, during the last session of Parliament, the borrowing powers of the Dublin Corporation were increased to the extent of £600,000. Therefore, the city now proposes to spend a quarter of a million for the housing of the extremely poor. Then we have Lord Iveagh's celebrated scheme which will also involve the expenditure of another quarter of a million sterling. By this scheme the Bull-alley area is being cleared while the Corporation takes up the adjoining district, so that a vast clearance will be accomplished on the slope from the Castle to St. Patrick's Cathedral, and some of the worst alleys, tortuous streets, and filthy and unhealthy houses will be swept out of existence. These will be replaced by broad streets and model dwellings. Lord Iveagh in his district proposes to built not only tenement houses, but also a bath house and a concert-hall, so that there shall be some local attractions and entertainments which will render the lives of the poor people more refined and joyful.

It will thus be seen that something is being done to meet the grievances which I have denounced. Considerable expense has already been incurred to clear insanitary areas, and these have been leased to public companies for the purpose of erecting artisans' dwellings, or else the corporation itself has built such tenement houses on the sites. In Coombe street and Plunket-street £57,689 have been spent for this purpose and yet much remains to be done here. The 144 tenements in Benburb-street cost £27,273; in Bow-lane 85 tenements cost £10,004; in St Joseph-place 80 one storey self contained cottages cost £25,500. At Blackhall-place and North King-street 85 tenements cost the municipal authorities £12,000. Yet when contemplating the poverty, wretchedness, and dirt of the town it is difficult to realise that so much has already been accomplished; and in some respects it must be confessed that there has been gross neglect. For instance, there is only one public washhouse in the city, and it has been closed now for some considerable time. It is argued with some show of reason that the people are not as dirty as they seem, but very few opportunities are provided for them to be clean. The fact that little boys crowd in the summer months to bathe in the sewage-polluted Liffey shows that if they had better opportunities they would not be so dirty. Thus, when in St. Stephen's green the ornamental waters were provided women from the neighbourhood brought their children to bath them here. It must also be borne in mind that the large houses now so generally let out as tenement dwellings were in most cases built a hundred or more years ago. The water-supply then installed was meant to provide for one family only, and what was considered sufficient a hundred years ago would be deemed quite insufficient even for a single family to-day. Yet in one of these houses I counted as many as 15 different families. The water is generally obtained from a tap in the back-yard, there is no delivery upstairs, and the rooms are so crowded that there is no space for tubs and the washing of linen, to say nothing of the trouble of bringing large quantities of water upstairs and the difficulty of heating the same. Thus the washing of linen is very generally neglected. In many of these old houses, also, there are no back kitchens, sculleries, boilers, or washhouses. How, then, are the poor tenants to wash their linen? Under such circumstances it would be natural to expect that there would be an extra supply of public washhouses, and yet the reverse is the case. It is difficult to find an excuse for such neglect. Another cause of the prevalence of dirt is the innate modesty of the poor women. Huddled together in crowded tenements they have not sufficient privacy and are too much afraid of indecently exposing themselves to wash properly. Hence there is a widespread prevalence of vermin, and a great many of the poor who go to the hospitals are found to be covered with lice.

Where a better example might be given which would serve as a lesson in cleanliness, this is too often neglected. Thus I have received many complaints as to the condition of some of the railway-station lavatories, where unpleasant odours prevail and the woodwork is soaked with urine and the closet-pans are caked with filth, and accumulations of dust contaminated with organic matter are allowed to remain. Many of the lodging-houses are far from clean, the mattresses are rarely aired and exposed to the sun, as is the common custom on the continent. Too often the beds are not properly made, but simply covered over while still warm. The cabs are badly cleaned. The shop-front windows are dirty and dingy. The street pavements are often insufficiently washed, while the cabstands are not infrequently surrounded by fœtid matter that all helps to render the streets unpleasant and to foul the subsoil. Consequently such examinations of the subsoil as have been made reveal a dangerous state of contamination. But such investigations are few and far between. In England the Local Government Board has the financial means by which it is able to despatch expert investigators wherever epidemics may occur. This is not so in Ireland. Thus some time ago there were epidemics at the creameries where the Irish farmers send their milk to be converted into butter by mechanical processes This is a sort of coöperative arrangement managed by the Irish Agricultural Society but it was menaced with ruin by the outbreak of typhoid fever. The medical members of the Irish Local Government Board wished to have some bactériological examinations in order to see whether, if the typhoid bacillus was in the milk, it could pass through the centrifugal machine and find its way into the skimmed milk or the butter, but the Treasury flatly refused a money grant for this purpose. In England bacteriological experts are employed by the Local Government Board and paid proper fees. Not so in Ireland, and yet this is but a trifling outlay in comparison to the very great service to be rendered. For the same reason, water cannot be analysed in Ireland under the auspices of the Local Government Board. This Board has no laboratory of its own and no funds to employ outside experts. Though attention has been drawn to this matter on several occasions, the Treasury seems incapable or unwilling to understand that this is really a serious grievance. No one can deny the importance of carefully watching over the water supply and milk-supply. In Dublin there are many dairies badly situated and close to dwelling-houses. There used to be one such dairy, with some 200 cows, close under the walls of the Richmond Hospital. The stench coming from it seriously inconvenienced the patients. Protests of course were made. The city corporation for a time exacted the more prompt removal of the manure, but they had no powers other than that of merely seeing that the dairy was kept fairly clean. The hospital authorities were finally compelled to buy out the dairy and thus only were they able to get rid of the nuisance.

Slaughter-houses and dairies, and the food supply generally, need a much more strict supervision. Then the schemes for the re-housing of the poor, extensive as they are, will not suffice to solve the difficulty. Much more also must be done to teach the people how to live decent lives. The women especially need to be taught how to wash, how to sew, and how to cook. It is a well-known saying in Ireland that God makes the food and the devil cooks it. Practical lessons in domestic economy should be more extensively given in the schools and no one should be allowed to open a school unless ample means for washing are provided. The Irish Public Health Act of 1878 contains many excellent provisions, but these are not strictly enforced. Party politics, personal influences, and religious antagonism play far too large a part in matters which should in no wise be connected with such subjects. The technical aspects of the problems to be solved are too often set aside in favour of party considerations. This fault may be found doubtless in all countries, but it is especially accentuated in Ireland and has done much to prevent progress on practical lines. But in the face of the terrible death-rate which has now prevailed so long in Dublin there should arise a strong and united demand for reform, and reform for its own sake quite apart from all party or factious considerations.

NOTES FROM INDIA.

(*From our Special Correspondent.*)

The Report of Native Assistant Surgeons upon Plague in Calcutta.—The Report of the Plague Commission.—Novel Medium for Plague Cultures.—Further Outbreak of Plague in Bombay City.—The Progress of the Epidemic.—Famine and Plague.—Strengthening the Indian Medical Service

THE question was put at the recent meeting of the Bengal Legislative Council—"Will the Government be pleased to appoint a committee of expert medical men to report if the cases now occurring and reported to be plague cases are cases of real bubonic plague?" The action of the Government has just been made public and the answer to the above question was as follows: "A few weeks ago the Lieutenant-Governor arranged to depute two specially selected assistant surgeons for a time to test the correctness of the reports of plague cases in Calcutta. The inquiry is not yet complete, but so far it goes to show that unfortunately cases of genuine plague unquestionably do exist in the town." This means that two assistant surgeons were sent about the city to inquire into, and report upon, cases which were at the same time being investigated by the regular plague medical staff. There is not a medical man in Calcutta, native or otherwise, who has had the opportunity of gathering experience of plague enjoyed by the regular staff. It is true that few cases are seen during life by medical men and still fewer by really competent judges, but undoubted cases continue to "crop up" and there are a large number of very suspicious deaths. There have been 170 deaths in Calcutta during the past three weeks in excess of the average and there is no particular disease prevalent to account for the increase. There have been 188 deaths returned as plague. Under these circumstances the additional inquiry might seem to show a want of confidence by the Government in its own officers. But there is a broader view which can be taken—viz., that the Indian Government desire to satisfy the natives through the medium of native medical men as to the exact state of affairs. With the returns which have been published week after week it is impossible to suppose that the disease has been eradicated.

The report of the Plague Commission, which was expected wo or three months after the termination of the hearing of the evidence, is being delayed owing to friction between the medical and administrative sections of the commission. It is said that drafts drawn by the former are rejected by the latter and *vice versâ*. The medical members state that the measures for dealing with plague ought to be carried out by men specially trained to diagnose and deal with the disease rather than by laymen who have had no such training. The others hold that the administration of the measures prescribed by Government, the building of hospitals, and the construction and organisation of segregation camps are more efficiently done by trained administrators and business men, medical officers of course having the care of the sick. Although they do not agree upon their report the commission is in accord regarding some minor points. One of these recommendations is that the disinfection of passengers at *railway stations should be discontinued, experience* having shown that it does not prevent the dissemination of plague from any given centre and uselessly inconveniences and annoys those subjected to the process. In view of the importance of safeguarding the foreign trade of the country it is essential that plague shall not be carried abroad by sea-going ships or steamers and that passengers bound for foreign parts shall be subjected to the strictest examination. It is understood that the commission considers that the port health officers should be strengthened so that the trying work can be done without imposing an undue strain on the health and endurance of those who have so devotedly discharged a responsible but very irksome duty.

In order to meet the religious scruples of a large section of the natives experiments have for some time past been conducted in order to ascertain whether or not the plague prophylactic obtained by growing the bacilli of plague in a medium manufactured from wheat was as effective as that made from meat in the ordinary manner. For rabbits at least the wheat peptone vaccine is as effective as that prepared from meat peptone. Only one experiment has been made, but there is no reason to suppose that human beings will react differently. It is suggested that publicity be given to this experiment, so that those communities which have religious scruples against the use of vaccine prepared from goats' flesh may be made aware that they can now be protected by the use of the wheat-peptone prophylactic. The new material is ready for distribution.

The recrudescence of plague in Bombay city has set in earnest and the weekly general mortality is now mo than double the normal. The plague returns give 278 death while the general mortality last week was 1552. 700 plag deaths would in some opinions be nearer the mark. It curious to note that measles, small-pox, and relapsing feve are all more prevalent than usual. Cholera, however, seem to keep subdued, while plague is rife. It is very satisfactory to find that inoculation is coming more into favour in Bombay city; 7179 persons were operated on last week.

The returns for the whole of India show a considerable further reduction in mortality from plague—the improvement being chiefly due to decrease in the number of deaths in the Bombay Deccan. Karachi has at last a clean sheet for one week. The Madras Presidency returns 42 deaths, Calcutta 50 deaths, Bengal Mofussil four deaths, the Punjab three deaths, the Central Provinces 13 deaths, Mysore State 184 deaths, and Rajputana two deaths. The total for the week is 1384. It will be seen, therefore, that plague is still widely distributed although not very active. The Saran district is the only one in Bengal which continues to return cases and last week there were nine seizures and four deaths. The returns for Calcutta are little to be relied on. The general mortality is higher than normal. The truth probably is that plague has been slumbering in Calcutta ever since the outbreak last spring. The abolition of railway examination is for the best, but shipping inspection, as the commission suggests, ought to be much more thorough. Many native boats escape detection and the examination of large numbers of passengers compels the officers to hurry over their work.

No sooner has plague subsided somewhat than famine scourges large tracts of land. The total number of people in receipt of Government relief in India is now close upon 2,250,000, 1,630,267 being in British territory and 596,291 in Native States. Western India is the sufferer from both calamities, and I regret to hear that the famine is even worse than was anticipated in the early part of the disease.

The short-handedness of the Indian Medical Service has been commented upon over and over again, so that with regard to the proposal for improving the reserve of the assistant surgeons in the army I am glad to find that a satisfactory conclusion has at last been arrived at. There is to be an addition of 155 assistant surgeons to the existing reserve.

Dec. 28th, 1899.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Anglo American Insurance Company.

AT the Birmingham Quarter Sessions on Jan. 21st a case of considerable interest was investigated before the Recorder. References to the matter have appeared already in your columns. A man, aged 35 years, was indicted for having attempted to obtain by fraud £100 from Dr. W. D. Lawrie, a surgeon living in one of the suburbs. It was stated that on Nov. 21st, 1899, the accused called upon Dr. Lawrie and represented that he was authorised by the Anglo-American Insurance Company to appoint medical officers in the principal towns of the country at a guaranteed annual salary of £100 on their agreeing to take shares to the extent of £100. He further stated that the company was registered, and produced a prospectus on which the names of the directors, who, he said, had invested £5000 in the company, were type-written. Among these was the name of Sir William Mac Cormac. A subsequent meeting was arranged, but in the meantime Dr. Lawrie consulted his solicitor, and a development took place in which the police made additional inquiries. It was shown at the trial that the prisoner and his agent had collected as much as £4200, principally from medical men. An able attempt was made by counsel to exculpate the prisoner, but the jury without hesitation found a verdict of guilty. The Recorder, in imposing a sentence of 15 months' imprisonment with hard labour, said that the prisoner had been convicted on the clearest evidence and that his was a most bare-faced attempt to defraud.

Assault on a Medical Man.

An extraordinary case was brought before the local magistrates at Rushall on Jan. 22nd. Dr. W. H. Whitehouse was summoned for assaulting a shoemaker at Pelsall on Jan. 8th. It was stated that Dr. Whitehouse was sent for to the house of the complainant on the morning of the above date; several other messages were subsequently sent and he ultimately arrived about half-past 5. The wife then told him that he was not wanted and that they had sent for another medical man. Dr Whitehouse turned to leave the house when the husband came downstairs and refused to allow him to leave until he had apologised. This he refused to do. This was the occasion of a combined attack by the woman with a poker, the husband with his fists, and a small boy who rendered effective service by kicking the doctor's shins. The case against Dr. Whitehouse was rightly dismissed, and the cross-summonses were then heard against the man and his wife for assaulting him. Evidence was given as to the injuries, and the defendants were fined £2 4*s.* each, including costs, or a month's imprisonment.

The Degradation of Consulting.

This scheme against which so strong a protest was raised by the profession, supported by the medical press, has not been allowed to slumber. It is stated that the committee of the Birmingham Medical and General Consultative Institute, under the auspices of the Hospital Saturday Committee, have made material progress with their arrangements. An appeal through the lay press of some of the larger cities has brought a number of responses from applicants willing to take the post of consultant, so much so that it has been not easy to make a choice among them. The selected gentlemen have been interviewed and an appointment has been made in which the committee express their entire confidence and which they think will give satisfaction to all concerned. A suite of rooms will be taken in a central position and as soon as possible the details set going. The scheme has met with hostility upon just grounds from the local members of the profession, and I am not prepared to envy the recipient of the committee's favours.

Medical Charities and War Funds.

In common with many benevolent institutions the medical charities are feeling the competition with the numerous efforts being made to help those connected with the war in South Africa. At the annual meeting of the Hospital for Children held on Jan. 22nd it was alleged that a distinct difference was being felt from the war fund appeals to private charity. The report showed that the number of patients for the year was 15,392, as against 14,565 in 1898. The number of out-patients was 14,164. The detention rate for the year was 19·1 days. The death-rate, calculated on 1028 patients treated to the termination of their cases, was 6·2 per cent. The average cost of patients per week was 3*s.* 1*d.*, while that of the officers was 6*s.* 10*d.*, as against 7*s.* 6½*d.* in 1898. The donations had increased by £226 while legacies of £2796 had been received. The report was full and concise and the institution is in a condition to appeal with every prospect of confidence for additional subscribers.

Jan 23rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Finances of Manchester Medical Charities.

A PAPER was read recently at the meeting of the Manchester Statistical Society by Mr. F. Brocklehurst, a member of the City Council, on the Medical Charities of Manchester and Salford. He summarised with a good deal of difficulty the figures obtained from the reports of 20 charities. Each institution gives its information in its own way, while a few of them, for instance, give the number of beds or the cost per patient treated. If the different authorities would agree to a uniform plan of presenting their statistics something would be gained by the charities and the public. Six only of the 20 give any information as to the residences of the patients. Some months ago it was stated that 40 per cent. of the patients treated at the infirmary came from outside districts, contributing little or nothing to the charity; and this is no doubt true of most of the other institutions. Mr. Brocklehurst estimates that, taking the whole of the charities, one-fourth of the cases treated during the year were from the outside. This would be regarded with equanimity but that so many of the medical charities carry on their work "in a condition of chronic insolvency." He gives 11 hospitals (among them the Salford Royal Hospital and Dispensary, the Clinical Hospital for Women and Children, Ancoats Hospital, St. Mary's Hospital, the Manchester and Salford Hospital for Diseases of the Skin, the Manchester and Salford Lock Hospital, the Southern Hospital for Diseases of Women and Children, and the Northern Counties Hospital for Incurables) with an aggregate deficit of £5796. And, in addition, the Eye Hospital has had to realise £2000 of its securities to pay its way; the Dental Hospital report says that all its securities have been sold to pay off the deficit; the bank overdraft of the Consumption Hospital was £560 and that of the Children's Hospital was £1550. A few years ago the Lewis trustees offered St. Mary's Hospital £70,000 for a new building, but the offer was so hampered with conditions and with a complex arrangement with the Southern Hospital that it came to nothing, while it seems to have injured both institutions and to have irritated the trustees. It is stated that the annual loss in the working of St. Mary's Hospital has "for many years" been £500 or £600. But such is the faith of hospital managers that in the face of all this a most expensive site at the corner of Oxford street and Gloucester-street, close to the Oxford-road Station—one of the worst that could have been chosen for a maternity hospital, being low and often enveloped in fog as well as most noisy—was purchased for the erection of a much larger building than the old St. Mary's Hospital. It was stated that in 1898 six charities had to take from their endowment funds £7000, and if bank overdrafts and adverse balances had been cleared off a further £5000 or £6000 would have been required. This year the local charities will no doubt suffer as a result of the drain on public and private resources in consequence of the war in South Africa, so that it would be too sanguine to hope for immediate improvement in their finances. If our men of business conducted their concerns as they manage the hospitals they would soon come to grief. There is no limit to the demands on medical charities, and it is difficult to push them aside; but it is a question whether too much is not being done for those who cry "Give, give," when they could help themselves; and whether our gigantic system of relief, with inefficient checks on abuse, is not doing as much harm as good by sapping all manly self-reliance and replacing it with the ethics of the chronic pauper. The difficulty, of course, is to help those in need and deserving, for the needy undeserving are well served by the Poor-law, while the sufficiently well-to-do are told to help themselves. Does this almost insolvent condition of so many of our hospitals obtain all over our country?

Ladies' Health Society.

The Ladies' Health Society, in union with the Manchester and Salford Sanitary Association, held its thirty-ninth annual meeting on Jan. 11th in the Manchester Town Hall. It was presided over by the Lord-Mayor. One or two fresh departures were made during the year. Special attention had been paid by the health visitors to giving the people information as to the infectious nature of consumption and how best to prevent its spread, guided, of course, by the instructions of Dr. Niven. These health visitors go from house to house, see the conditions under which the people are living, and are often able to improve them. They report defective drainage and insanitary arrangements to the authorities, give advice, often practical, in cases of illness—not interfering with the medical man I may hope—and instruct mothers in the feeding of infants. Sometimes they help in the actual cleaning of a room and give assistance in any way they can. All this work is directed and overlooked by the lady superintendents. But more help is needed. The area to be covered is too great for the resources of the society and many parts of the town are untouched. But, like many of our charitable and philanthropic societies, it lacks support, and even with the valuable aid given by the corporations of Manchester and Salford the expenditure exceeds the income. The honorary treasurer stated that with subscriptions of £297 they had practically a loss of £100. The Dean of Manchester drew attention to the fact that the income had not increased during the last 20 years. It is not a time to expect a great accession of subscriptions when special and urgent calls are so numerous, but if the hundreds in Manchester who give largely were supplemented by the many thousands who could give a little our hospitals and other agencies for the benefit of those who need help would soon be in a more flourishing condition. The Dean thought that many ladies would find recreation in the best sense for the mind and spirit, if not for the body, in going to and fro in the great working-class districts of Manchester, ministering not merely of their substance but also of their kindly sympathy.

Salford Workhouse Question.

At the meeting of the Salford Board of Guardians on Jan. 19th the question of the building of a new workhouse was under discussion. The estimate for the undertaking was £201,137, which was afterwards brought down to £194,771. There is also a scheme for providing cottage homes for the workhouse children which it is expected will cost not less than £50,000, and one of the guardians pointed out that if both were pushed forward at once their borrowing powers would be largely exceeded. In the end it was decided to defer the consideration of the plans for the workhouse until those for the cottage homes had been submitted. This seems a wise decision, for the removal of the children from the workhouse atmosphere—both mental and physical—to cottages where the pauper surroundings will be less obtrusive cannot but be good for them. And of course the removal of the children will greatly relieve the pressure on the workhouse and give, according to the testimony of one of the guardians, accommodation for 300 persons and meet all requirements for the next 10 years. If this be so the need for the immediate erection of a new workhouse is not apparent, but some members of public bodies are never happy unless they can be spending the ratepayers' money either wisely or unwisely.

Vaccination of Oldham Pauper Children.

At the meeting of the Oldham Board of Guardians on Jan. 11th it was stated that "it was a regular thing for the doctor to vaccinate children without receiving the consent of the parents." The chairman moved a resolution forbidding this and went on to say that "there was no doubt the medical fraternity were rushing the Vaccination Act to all intents and purposes," whatever this may mean. He said that "about £1000 a year would be spent by that board in administering the Act and he thought it was scandalous that that amount of money should be spent." Presumably the chairman would not think it scandalous if he aided and abetted an outbreak of small-pox.

Jan. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

AT a meeting of the managers of Edinburgh Royal Infirmary held on Jan. 22nd a donation was intimated from Mr. Thomas Aitken of Nivingston and 5, Grosvenor-crescent of the sum of £40,000. In consideration of this the managers agreed to name a ward the "Aitken Ward" and recorded in the minutes an expression of their deep gratitude to Mr. Aitken for his munificent donation to the infirmary and of their hope that he would be long spared to take an interest in the ward. Mr. Aitken is the manager of the London and Edinburgh Steam Shipping Company.

Hospital for Incurables in Dundee.

The Queen has graciously consented that the new hospital for incurables which has been established in Dundee to commemorate the Diamond Jubilee should be called "The Royal Victoria Hospital."

Typhoid Epidemic in Ayr.

The typhoid fever epidemic seems to be again increasing in the burgh of Ayr. The total number of cases is now 196. There have been 23 deaths in all, four of these having occurred since Jan. 1st. Nearly all the cases have come from the Newton and Wallacetown districts of the town.

Jan. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The City of Dublin Hospital.

MR. HENRY MOORE of Mercer's Hospital, who has recently left Dublin for service in South Africa, has been unanimously elected surgeon to the City of Dublin Hospital to fill the vacancy caused by the death of Dr. W. I. Wheeler. Mr Moore will assume his duties on his return from the Cape.

Death of the Registrar-General for Ireland.

Dr. Thomas Wrigley Grimshaw, for many years Registrar-General for Ireland, died from pneumonia on Jan. 23rd at Carrickmines, after an illness of only one week's duration. He was in his sixty-first year. Recently the duties of the Registrar-General—always of an important character in connexion with public medical, sanitary, and statistical subjects—were rendered particularly onerous owing to the very exceptional death-rate of Dublin. Dr. Grimshaw was a Fellow and ex-President of the Royal College of Physicians of Ireland and a consulting physician to a number of hospitals. He rendered most efficient service on many Government Commissions. It is recognised on all hands that his difficult duties were always discharged, not alone with conspicuous ability, but also with singular fidelity, tact, and courtesy. Dr. Grimshaw's death will be deplored by a very wide circle of his friends, while his loss as a prominent and most highly efficient public servant will be severely felt.

The Irish Hospital for South Africa.

The arrangements for Lord Iveagh's Irish Hospital for South Africa have now been completed. The hospital will be under the charge of Sir William Thomson, surgeon-in-chief; Mr. George Stoker, second surgeon; Dr. James Coleman, physician; and Dr. Alfred Friel of Waterford, surgeon. Sir William Thomson has arranged to leave for Cape Town on Feb. 3rd.

Infringement of the Vaccination Acts.

A curious case came before the Belfast police-court on Jan. 19th. The Belfast Poor-law Guardians summoned a man for not having his child (born in Ireland on May 9th, 1899) vaccinated. The man tried to get out of the difficulty by obtaining an exemption certificate made out in England.

This document came from the magistrates in Newcastle-on-Tyne and stated that the parent of the child, residing in Belfast, had satisfied them that he conscientiously believed that vaccination would be prejudicial to the health of his child. The Belfast magistrate having pointed out that at the time that this exemption certificate was made out in England the child was in Ireland (where it still resided), and that the Act under which conscientious objectors claim exemption does not apply to Ireland or Scotland, fined the man 10*s*. and 12*s*. 6*d*. costs.

Londonderry Asylum.
